Engineering Recommendation EREC S34

Draft Issue 2 2014

A GUIDE FOR ASSESSING THE RISE OF EARTH POTENTIAL AT ELECTRICAL INSTALLATIONS

Operations Directorate
Energy Networks Association
6th Floor, Dean Bradley House
52 Horseferry Rd
London
SW1P 2AF

This document has been prepared for use by members of the Energy Networks Association to take account of the conditions which apply to them. Advice should be taken from an appropriately qualified engineer on the suitability of this document for any other purpose.

139 **Foreword**

140 This Engineering Recommendation (EREC) is published by the Energy Networks Association
141 (ENA) and comes into effect from <Month, 2014>. It has been prepared under the authority
142 of the ENA Engineering Policy and Standards Manager and has been approved for
143 publication by the ENA Electricity Networks and Futures Group (ENFG). The approved
144 abbreviated title of this engineering document is "EREC S34", which replaces the previously
145 used abbreviation "ER EREC S34".

146

147 **Introduction**

148 This Engineering Recommendation is the technical supplement to TS 41-24 (2014),
149 providing formulae, guidelines and examples of the calculations necessary to estimate the
150 technical parameters associated with Earth Potential Rise (EPR).

151 TS 41-24 provides the overall rules, the design process, safety limit values and links with
152 legislation and other standards.

153 **1. Scope**

154 This document describes the basic design calculations and methods used to analyse the
155 performance of an earthing system and estimate the earth potential rise created, for the
156 range of electrical installations within the electricity supply system in the United Kingdom, as
157 catered for in TS 41-24. Modification to the calculations and methods~~formulae and routines~~
158 may be necessary before they can be applied to rail, industrial and other systems.

159 ~~At operating voltages below 132kV, due to the large number of installations, standard~~
160 ~~spreadsheet based routines have been developed to help address the volume of work~~
161 ~~involved. At higher voltages, especially for transmission systems, 'site or project specific'~~
162 ~~studies are generally necessary. These systems consist of a smaller number of installations,~~
163 ~~the earth fault currents are high and there are multiple sources (including large generation~~
164 ~~and/or transformer infeeds.) Their power circuits, in particular those using buried cable, are~~
165 ~~usually custom designed. Therefore the routines provided here are only suitable for first~~
166 ~~estimates or feasibility studies.~~

167 ~~Most of the content of this document addresses electricity substations at 132kV and below,~~
168 ~~i.e. within sub-transmission and distribution systems.~~

169 ~~The formulae and routines in this document are only applicable to UK public electricity supply~~
170 ~~distribution and transmission networks and their associated equipment. Modification to the~~
171 ~~formulae and routines may be necessary before they can be applied to rail, industrial and~~
172 ~~other systems.~~

173 ~~5.~~2. **Normative references**

174 TS 41-24 contains the main list of reference documents. Only reference documents used for
175 EREC S34 and not listed in TS 41-24 are shown below.

176 **Standards publications**

177 BS EN 50522: 2010: Earthing of power installations exceeding 1kV a.c.

178 TS 41-24 (2015): Guidelines for the Design, Installation, Testing and Maintenance of Main
179 Earthing Systems in Substations.

180 BS EN 60909-3: Short-circuit currents in three-phase a.c. systems. Currents during two
181 separate simultaneous line-to-earth short-circuits and partial short-circuit currents flowing
182 through earth

183 **Other publications**

To be added later

184

185 **6.3.   Terms and definitions**

186 **3.1 Symbols used**

187 Symbols or a similar naming convention to BS EN 50522 have been used and they are set
188 out in Appendix A. Where these differ from the symbols used in earlier versions of this
189 document, the previous symbols are shown alongside the new ones, to assist when checking
190 previous calculations and formulae.

191 **3.2 Formulae used for calculating earth installation resistance for earthing studies**

192 The most common formulae for power installations are included in Appendix B. These are
193 generally used to calculate the resistance of an earth electrode system comprising of
194 horizontal and/or vertical components or potentials at points of interest.

195 When using formulae, to calculate earth resistances, caution is necessary, because they do
196 not normally account for proximity effects or the longitudinal impedance of conductors.

197 For first estimates, the overall impedance Z_E of separate electrodes with respect to reference
198 earth, is taken as the sum of their separate values in parallel. For the example shown in
199 Figure 3.1, this would be:

200 $$Z_E = \left(\frac{1}{R_{Es}} + \frac{1}{R_H} + \frac{1}{Z_{CH1}} + \frac{1}{Z_{CH2}} + \cdots \right)^{-1}$$

> **Commented [DC3]:** ES not Es

201 (see Appendix A for description of symbols used)

202 In reality, Z_E will be higher if the separate electrodes are close enough that there is significant
203 interaction between them (proximity effect).

204 Proximity effects can be accounted for in most advanced software packages. When relying
205 on standard formulae, the following techniques can help to account for proximity when
206 calculating Z_E:

207 • Include any radial electrodes that are short in relation to the substation size, into the
208   overall calculation of the earth grid resistance.

209 • For radial spur electrodes or cables with an electrode effect, assume the first part of its
210   length is insulated over a distance similar to the substation equivalent diameter.
211   Calculate the earth resistance of the remainder of the electrode/cable and add the
212   longitudinal impedance of the insulated part in series.

213 • For a tower line, assume that the line starts after one span of overhead earthwire (the
214   longitudinal impedance of this earthwire/span would be placed in series with the tower
215   line chain impedance).

216 A value of soil resistivity is needed and for the formula in Appendix B, this must be a uniform
217 equivalent (see TS 41-24, Section 8.1.) For soils that are clearly of a multi-layer structure
218 with significant resistivity variations between layers, the formulae must be used with caution
219 and it is generally better to use dedicated software that accounts for this to provide results of
220 the required level of accuracy.

221 **3.3 Description of system response during earth fault conditions**

222

223 **Figure 3.1 Earth fault at an installation which has an earthed tower line supply**
224 The arrangement shown in Figure 3.1 is based upon the example described in BS EN 50522
225 and will be explained and developed further in this document. The EPR is the product of
226 earth electrode impedance and the current that flows through it into the soil and back to its
227 remote source. The description below is to show how the fault current and associated
228 impedances are dealt with to arrive at the components that are relevant to the EPR.

229 The installation is a ground-mounted substation that is supplied or looped into an overhead
230 line circuit that is supported on steel towers and has an over-running earthwire. In this
231 simplified example, ~~the electrical energy is provided from one side only~~for clarity currents are
232 only shown on one of the infeed circuits and each tower line supports only one (three phase)
233 circuit.

234 The fault condition is a high voltage phase insulation failure to earth within the substation. It
235 is possible to model this situation with computer software such that all of the effects are
236 summated, calculated and results presented together. For traditional analysis in this
237 standard, the effects are de~~un~~coupled as now described.

238 The total earth fault current at the point of fault (I_F) that will flow into the earth grid and
239 associated components would be reduced initially by two components.

240 • The first component is that passing through the transformer star point earth connection
241 (I_N) and returning to source via the unfaulted phase conductors. For systems that are
242 normally multiply earthed, ie at 132kV and above, The total current excluding the I_N
243 component is normally calculated by summating the currents in all three phases ($3I_0$)
244 vectorially ~~at 132kV and above~~. The process is further described in Case Study 4. For
245 lower voltage distribution systems, I_N is normally zero or sufficiently low to be ignored in
246 calculations.

247 • The second reduction is due to coupling between the faulted phase and continuous
248 earth conductor (see 4.3 below.) This part of the current is normally pre-calculated for
249 standard line arrangements or can be individually calculated from the support structure
250 geometry, conductor cross section and material. A similar procedure is followed for a

251 buried cable~~, for which spreadsheet routines have now been developed~~.. Another
252 approach is to use a reduction factor (termed r_E) based on the specific circuit geometry
253 and material.

254 Once these components have been removed, the situation is shown in Figure 3.2. The earth
255 current (I_E) is treated as flowing into the earth network, which in this example contains the
256 substation earth grid (resistance R_{ES}) and two 'chain impedances', of value Z_{CH1} and Z_{CH2}.
257 The two chain impedances are each a ladder network consisting of the individual tower
258 footing resistance R_{ET} in series with the longitudinal impedance of each span of earthwire.
259 They are treated as being equal if they have more than 20 similar towers in series and are in
260 soil of similar resistivity. The overall impedance of the electrode network is Z_E and the current
261 (I_E) flowing through it creates the Earth Potential Rise (U_E.)
262
263 The analysis of the performance of the system described follows the process shown in the
264 design flow diagram (Appendix C.) The case studies in section 6 illustrate this process for a
265 number of examples of increasing complexity.

266
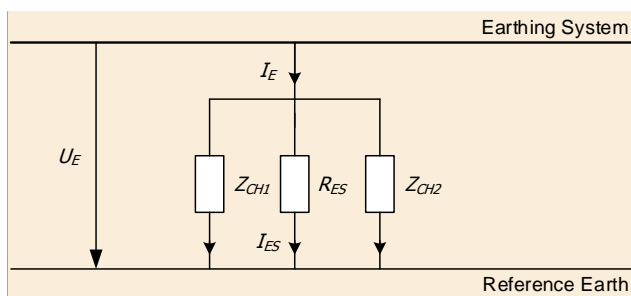

Figure 3.2 Equivalent circuit for analysis

267

268

269   7.4.   **Earth fault current studies**

270   This section describes how to use the fault current data (calculated using the methodology
271   set out in BS EN 60909 and guidance from TS 41-24, Section 8.2) for earth potential rise
272   purposes.

273   **4.1   Earth fault current**

> **Commented [DC7]:** Check for consistency of terminology etc against 41-24

274   Source earth fault current values (such as the upper limit with neutral earth resistors in place)
275   may be used for initial feasibility studies, but for design purposes, the value used should be
276   site specific, i.e. should account for the fault resistance and longitudinal phase impedance
277   between the source and installation.

278   Once the fault current is known, the clearance time for a "normal protection" operation (as
279   defined in TS 41-24), at this level of current should be determined and the applicable safety
280   voltage limits obtained from TS 41-24, Section 6. This basis of a normal protection operation
281   is used for the personnel protection assessment. Design measures should be included within
282   installations to afford a higher level of protection to personnel in the event of a main
283   protection failure.

284   For signalling protection and telecommunication equipment immunity studies in distribution
285   systems, the steady state rms fault current values are normally used. At some installations,
286   particularly where there are significant generation in-feeds, consideration should be given to
287   sub-transient analysis. This is especially important where vulnerable equipment (such as a
288   telephone exchange) is installed close to a generation installation.

289   For calculation of the EPR, it is the ground return component of the fault current (I_E) that is of
290   concern. On some transmission systems, this can be greater for a phase-phase-earth fault
291   (compared to a straightforward phase-earth fault) and where applicable, this value should be
292   used for the EPR calculation.

293   **4.2   Fault current analysis for multiple earthed systems**

294   The methodology followed in this document assumes that the earth fault current at the
295   substation (possibly at a defined point in the substation) has been separately calculated
296   using power system analysis tools, symmetrical components or equivalent methods.
297   Depending upon the complexity of the study, the data required may be a single current
298   magnitude or the full three phase currents in all supply circuits in vector format.

299   **4.3   Induced currents in parallel conductors**

300   The alternating current that flows in a conductor (normally a phase conductor) will create a
301   longitudinal emf in conductors that lie in parallel with it. These are typically cable metal
302   screens (lead sheath, steel armour or copper strands), earthwires laid with the circuit, metal
303   pipes, traction rails or the earthwires installed on overhead lines. This emf will increase from
304   the point of its earth connection as a function of the length of the parallelism and other
305   factors (such as the separation distance.) If the remote end of the parallel conductor is also
306   connected to earth, then a current will circulate through it, in the opposite general direction to
307   the inducing current.

308   The current that flows (returns) via the cable sheath or earthwire during fault conditions can
309   be large and it has the effect of reducing the amount of current left to flow into the ground via
310   the electrode system, resulting in a reduced EPR on it.

311   The following sections provide methods show how to account for these return currents.

4.3.1 Simple circuit representation for initial estimates

For an overhead line with a single earthwire, or a single cable core and its earth sheath, the formulae below approximate the ground return current (I_E). The main assumption is that the circuit is long enough such that the combined value of the earthing resistances at each end of the line are small compared with z_s, or for cable, small compared with r_c.

For an overhead line:

$$I_E = k(I_F - I_N) \quad \text{where } k = \left(1 - \frac{z_{mp,s}}{z_s}\right)$$

Appendix E gives calculated values of I_E presented as a percentage value of I_F and phase angle with respect to I_r for a range of the most commonly used overhead line constructions at 132 kV, 275 kV and 400 kV.

For a single core cable:

$$I_E = k(I_F - I_N) \quad \text{where } k = \left(\frac{r_c}{z_c}\right)$$

The equations are not sufficiently accurate for short circuits (less than 1km) and the results are sensitive to low values of terminal resistance.

4.3.2 More realistic circuit representation to improve the accuracy of calculations

More complete ~~equations~~ formulae are presented in Appendix D. They require a number of circuit and cable specific factors to provide sufficiently accurate results. These have been included in Table A4.1 (Appendix D), for a representative sample of cables.

~~To cater for the range of power cables used in the UK electricity industry, circuit factors have been calculated and introduced into software routines.~~ The case studies have been selected to show how to use the ~~equations~~ formulae and ~~calculations~~or routines for a range of different scenarios. The ~~software routines~~calculations generally provide results that are conservative, because parallel circuit earthwires or cables are not included in the circuit factors. The parallel earthwires or cables can be included in the circuit factors and their use in the formulae of Appendix D will then provide more accurate results.

Where single core cables are used for three phase circuits, the calculations are based upon them being installed in touching trefoil formation, earthed at each end. Where the cables are not in this arrangement, the results may be optimistic and correction factors need to be considered, (see. 4.3.3 and Appendix H.)

The ~~equations and routines~~formulae and calculations are sufficiently accurate for use at 11kV and 33kV on radial circuits. Circuit factors have not been included for 66kV cables because so little of this is present within DNOs, typically only for initial lengths of predominantly overhead line circuits. First estimates for these cables can be made using a similar 33kV cable.

At 132kV, the ~~equations and routines~~formulae and calculations are sufficiently accurate for use in feasibility studies, especially for single end fed "all cable" circuits. They should normally provide conservative results. This is because the circuit factors calculated are for the cable construction that provides the highest ground return current, due for example to having the highest longitudinal sheath impedance and/or weakest mutual impedance between the faulted and return conductors. This would result from a cable with the smallest cross section area of sheath or the least conductive material (such as all lead rather than composite, aluminium or stranded copper) and thicker insulation (older type cables which

355 subsequently have a slightly weaker mutual coupling between the core and sheath~~.~~)~~.~~   If
356 further refinement or confidence is required, the circuits should be modelled with the
357 appropriate level of detail and the work would normally show that a lower ground return
358 current is applicable (i.e. more current returning via the cable screens or metallic routes.)

359 The formulae and calculation ~~routine~~s cater for simple overhead line circuits where there is
360 no associated earthwire. For steel tower supported circuits that have an over-running
361 earthwire, account is made of the induced current return by using the table in Appendix E.

362 ~~Hybrid type C~~circuits that contain both underground cable and earthed overhead tower line
363 construction are not presently ~~catered for~~addressed and need to be analysed on a site
364 specific basis. ~~It is anticipated that future research work will provide some simplified~~
365 ~~calculation methods for such circuits.~~

4.3.3 Amending calculations to account for increased ground return current in single core circuits that are not in flat or trefoil touching arrangement

368 The fault current analysis routines for single core cable have assumed that the cables are
369 earthed at each end and in touching trefoil formation.

370 In many practical situations, the cables are separated by a nominal ~~amount~~distance, either
371 deliberately (to reduce heating effects) or inadvertently (for example when installed in
372 separate ducts.)

373 When the distance between the individual cables is increased, the coupling between the
374 faulted and other two cables is reduced. This in turn results in more current flowing through
375 the local electrodes (R_B and R_A) and an increase in the EPR at each point.

376 Some fault current studies for 11kV and 132kV cables where the cables are in touching
377 trefoil, touching flat or the spacing is 3 x D (i.e. 3 x the cable diameter) are included in
378 Appendix H.

379 These show that, compared to touching trefoil, the ground return current component
380 increases for the other arrangements as:

381 • The cable length increases
382 • The cable screen cross sectional area (or conductivity) increases

383 For a flat arrangement or 3 x D spacing, the ground return current is seen to increase by up
384 to about 6% to 7%. Accordingly, if the cables are not touching, the ground return current and
385 EPR may be adjusted by this amount or a more accurate amount deduced from the
386 information in Appendix H or more detailed site specific analysis. If this effect is not
387 accounted for, the results will be optimistic.

388   ~~8.~~ 5.   **Calculations associated with external and internal impact of the EPR**

389   **5.1   Calculation of external impact zones**

390   **5.1.1 Potential contours, such as hot zone**

391 The EPR at the substation creates potentials in the soil external to the substation and equation
392 P7 in Appendix B can be used to provide an estimate of the distance to the contour of interest.

393 The formula is as below:

394
$$Z_x = \sqrt{\frac{A}{\pi}} \left[\left(sin\frac{V_x\,\pi}{2\,U_E} \right)^{-1} - 1 \right]$$

395 Where Z_x is the distance to the point from the edge of the grid to where the voltage is V_x, and
396 A is the area of the grid in square metres.

397 As emphasised elsewhere in this document, this and other formulae are restricted in
398 accuracy by their assumptions of a symmetrical electrode grid and uniform soil resistivity.
399 More accurate plotting of contours is possible using computer software or site
400 measurements.

401   **5.1.3 External step potential**

402 The step potential is the potential difference between two points that are 1m apart. This can
403 be derived as the difference in calculated surface potential between two points that are 1m
404 apart (Appendix B Formula P5.)

405
$$U_{vs} = \frac{\rho I_F}{2\pi r} \left(\arcsin\frac{r}{x} - \arcsin\frac{r+1}{x} \right) \quad \text{where} \quad r = \frac{\rho}{4R_E}$$

> **Commented [DC9]:** Move until after touch potentials

406   **5.2   Calculation of touch potentials ~~within and adjacent to the installation~~**

407 Formulae are provided in Appendix B to provide the following:

- 408 External touch potential at the edge of the electrode (separately earthed fence) – P1.

- 409 External touch potential at the fence (separately earthed fence) – P2.

- 410 External touch potential at fence where there is no external perimeter electrode
411 (bonded fence arrangement) – P1.

- 412 External touch potential at fence with external perimeter electrode 1m away (bonded
413 fence arrangement) – P3.

- 414 Touch potential within substation (under consideration.)

> **Commented [RW10]:** a suitable formula is needed

415

416 **5.3   Transfer potential to LV systems where the HV and LV earthing are separate.**

417 **5.3.1   Background**

418 This issue predominantly concerns distribution type substations (typically 11kV/LV in the UK)
419 where the HV and LV earthing systems are separate. Another application is where an LV
420 earthing system is situated within the zone of influence of a Primary Substation with a high
421 EPR. Previous guidance was based upon the presence of a minimum 'in ground' separation
422 between the two electrode systems being maintained (distances of between 3m and 9m
423 have historically been used in the UK). Operational experience suggested that there were
424 fewer incidents than would be expected when the separation distance had been encroached
425 on multiply earthed (i.e. TNC-S or PME arrangements).   Theoretical and measurement
426 studies (reference xx – see Bibliography) (M. Davies, T. Charlton, D. Baudin, 'New Design
427 Methods to Achieve Greater Safety in Low Voltage Systems During A High Voltage Earth
428 Fault', CIRED Conference, Frankfurt, June 2011) showed that the minimum separation
429 distance is a secondary factor, the main ones being the size and separation distance to the
430 dominant or average LV electrode (where there are many small electrodes rather than one or
431 a few large ones). We refer to this as the 'centre of gravity' of the LV electrode system.

432 **5.3.2   Basic theory**

433 Equations are available Appendix B (P6) to calculate the surface potential a given distance
434 away from an earth electrode. Three different electrode shapes are included as follows:

435 a)   A hemispherical electrode at the soil surface

436   b)a)   A vertical earth rod
437   c)b)   An earth grid – approximated to a horizontal circular plate.

438

439 The surface potential calculated at a point using these formulae is equal to the transfer
440 potential to a small electrode located at that point because an isolated electrode would
441 simply rise to the same potential as the surrounding soil.

442 When two or more electrodes are connected together, previous investigations have shown
443 that the transfer potential on the combined electrode is an 'average' of the potentials that
444 would exist on the individual components. This 'average' was found to be 'skewed' towards
445 the surface potentials on 'dominant' electrodes, i.e. those having a lower earth resistance
446 due mainly to being larger.

447 A simple method is required to explain and then account for this 'averaging' effect. Figure 5.1
448 shows a simple arrangement of a HV earth electrode and two nearby LV earth rods (A and
449 B) which are representative of typical PME electrodes.

450 The three electrodes are located along a straight line and the soil surface potential profile
451 along this route is also approximated in the figure.
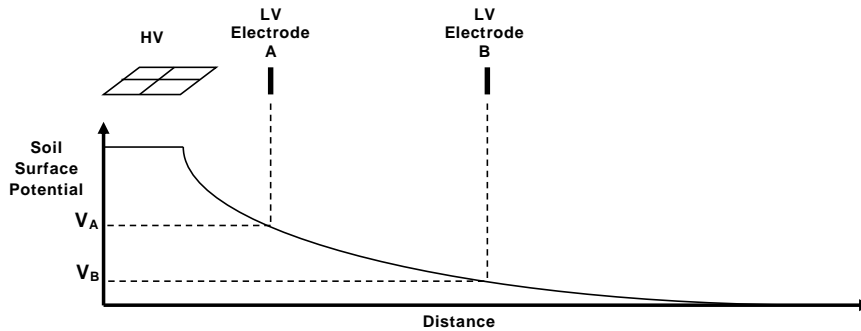

452 **Figure 5.1 Surface potential near a simple HV and LV electrode arrangement**

453 When there is an EPR (Earth Potential Rise) on the HV Electrode the LV Electrodes, A and B
454 will rise to the potential of the local soil, i.e. the surface potential. In Figure 5.1, these are
455 defined as V_A and V_B. The LV Electrodes are clearly at different potentials and this depends
456 on the distance away from the HV electrode.

457 Once A and B are connected together (for example by the sheath / neutral of an LV service
458 cable) the potential on them will change to an 'average' value, between V_A and V_B. In simple
459 cases where A and B are of a similar size (and hence earth resistance in soils of similar
460 resistivity), the average potential is accurate but where electrodes A and B are of significantly
461 different sizes the 'average' is 'skewed' towards the dominant one (the larger one, i.e. that
462 has the lowest earth resistance).

463 The 'averaging' effect can be explained by considering an equivalent circuit for the combined
464 LV electrodes as shown in Figure 5.2. V_A and V_B are the local soil surface potentials and VT
465 is the overall potential on the combined LV electrode. Electrodes A and B have earth
466 resistances of R_A and R_B respectively.
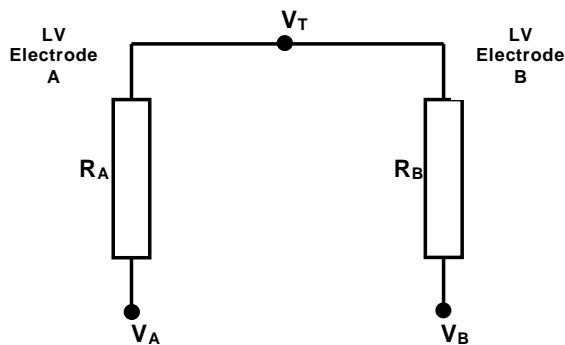

467 **Figure 5.2 Equivalent Circuit for Combined LV Electrodes A & B**

468 The circuit is a potential divider and the voltage on the combined LV electrode (V_T) can be
469 expressed by:

470 $$V_T = \frac{V_A R_B + V_B R_A}{R_A + R_B}$$

471 If the LV electrode earth resistances are equal ($R_A = R_B$) then this equation reduces to $V_T =$
472 ($V_A + V_B$)/2, i.e. the average of the two potentials.

473 5.3.3 5.3.2 **Examples**

474 **(a) Equal LV Electrode Earth Resistances**

475 It is useful to consider a worked example where assumed typical values have been used in
476 the circuit from Figure 5.2 and the transfer voltage has been calculated. Figure 5.3 shows
477 the circuit together with the calculated parameters.

478
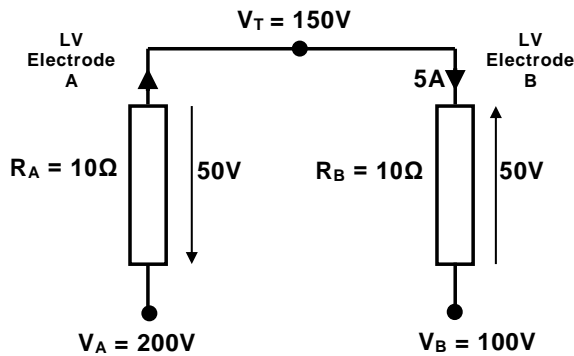

479 **Figure 5.3 Example – Two Electrodes of Equal Resistance**

480 From Figure 5.3, the surface potential experienced by electrodes A and B effectively act as
481 voltage sources. Because electrodes A and B are connected together via an above ground
482 conductor (assumed to have negligible resistance compared to the earth resistances) the
483 potential difference of 100V across the total series resistance of 20Ω causes a current of 5A
484 to circulate through the electrodes. This creates a voltage drop of 50V across the earth
485 resistance of A which is negative with respect to the local surface potential. This reduces the
486 local electrode potential (by 50V with respect to the local soil potential). Conversely at
487 electrode B there is a 50V potential drop across the earth resistance which increases the
488 electrode potential by 50V with respect to the local soil potential.

489 This is consistent with the previous work and explains the changes in surface potential
490 contours around combined LV electrodes.

491 **(b) Unequal LV Electrode Earth Resistances**

492 Figure 5.4 shows a similar example but where Electrode B has an earth resistance 5 times
493 lower than Electrode A.

494
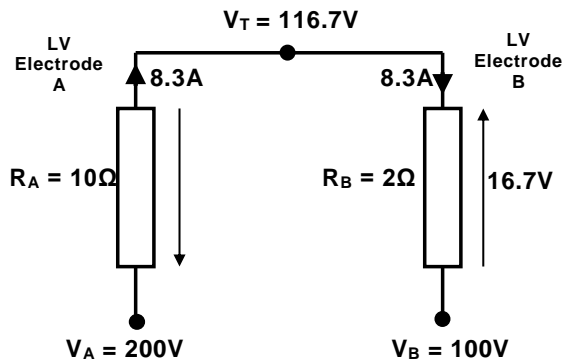

495 **Figure 5.4 Example - Two Electrodes of Unequal Resistance**

496 It can be seen that the potential on the combined LV electrode is much lower than the
497 average value of 150V. Because Electrode B has a much lower resistance it has a smaller
498 volt drop across it and so the combined electrode potential is closer to the voltage on
499 Electrode B.

500 **(c) More than Two LV Electrodes**

501 A similar calculation process can be applied to combinations of more than two LV electrodes.
502 The equation below provides the combined electrode potential for three electrodes, A, B & C.

503 $$V_T = \frac{V_A(R_B R_C) + V_B(R_A R_C) + V_C(R_A R_B)}{(R_B R_C) + (R_A R_C) + (R_A R_B)}$$

504 The equation below allows a similar calculation to be made for four combined LV electrodes,
505 A, B, C & D.

506 $$V_T = \frac{V_A(R_B R_C R_D) + V_B(R_A R_C R_D) + V_C(R_A R_B R_D) + V_D(R_A R_B R_C)}{(R_B R_C R_D) + (R_A R_C R_D) + (R_A R_B R_D) + (R_A R_B R_C)}$$

507 Further equations for more than four combined LV electrodes can easily be produced by
508 continuing this pattern and would be best implemented via a computer programme
509 subroutine loop.

510 ~~5.3.4~~5.3.3   **Discussion**

511 This method has been found to provide a conservative estimate of transfer potential to LV
512 earthing systems when the HV earth resistance is reasonably accurate, ideally determined
513 by measurement. If calculated, conservative results are obtained if the equation for the earth
514 resistance of a hemispherical electrode is used.

515 The above method may also be applied to a horizontal electrode which may be represented
516 as a series of equally distributed vertical rods along its route. The coarsest representation is

517 to model the horizontal electrode as two short vertical rods, the first at the point on the
518 electrode nearest the HV electrode and the second at the furthest point. This method
519 provides a conservative estimate of the transfer potential to the LV electrode. The greater
520 number of rods used to model the horizontal electrode, the more accurate the calculated
521 transfer potential becomes.

522 The method described above has been found to be reasonably accurate (and conservative)
523 for soils with uniform resistivity and those where there is a lower resistivity deeper layer.
524 Care should be taken when applying to soils where there is a high resistivity deeper layer,
525 e.g. underlying rock, as transfer potentials may be underestimated and additional safety
526 factors may need to be applied.

527 Where there is a distributed HV electrode system, e.g. where there are extended HV cables
528 with bare sheaths in contact with the soil, the accuracy of this approach will depend on the
529 location of the LV electrodes relative to the HV electrode. The approach may be valid if the
530 LV electrodes are in the opposite direction to the HV electrode otherwise the transfer
531 potential will need to be calculated by more detailed methods.

532 For detailed analysis of complex HV or LV electrode shapes and highly non-uniform soil
533 resistivity structures the use of computer simulation software will be required.

534 ### 5.3.5 Application to real systems

535 The fact that the transfer potential is governed by the distance to the 'centre of gravity' of the
536 LV electrode system from the HV electrode has now been established, can help with the LV
537 electrode design to minimise transfer potential. From this perspective, the best method is to
538 install dominant parts of the LV electrode system as far as practicable from the HV electrode,
539 i.e. towards the extremities of the LV system.

540 ### 5.3.6 Worked example

541 Arrangement 1: Pole-Mounted 11kV/LV Substation

542 A typical pole-mounted 11kV substation arrangement is shown in Figure 5.5. The HV and LV
543 earthing systems are separated; in this example the transformer LV neutral/earth electrode is
544 located 9m away from the transformer HV earth electrode. A service cable provides an LV
545 supply to a dwelling located 50m away from the HV earth electrode and there is a LV PME
546 earth electrode at the property.

The HV Earth Electrode is assumed to be a 3.6m earth rod of 16mm diameter and the soil resistivity is assumed to be 75Ωm.
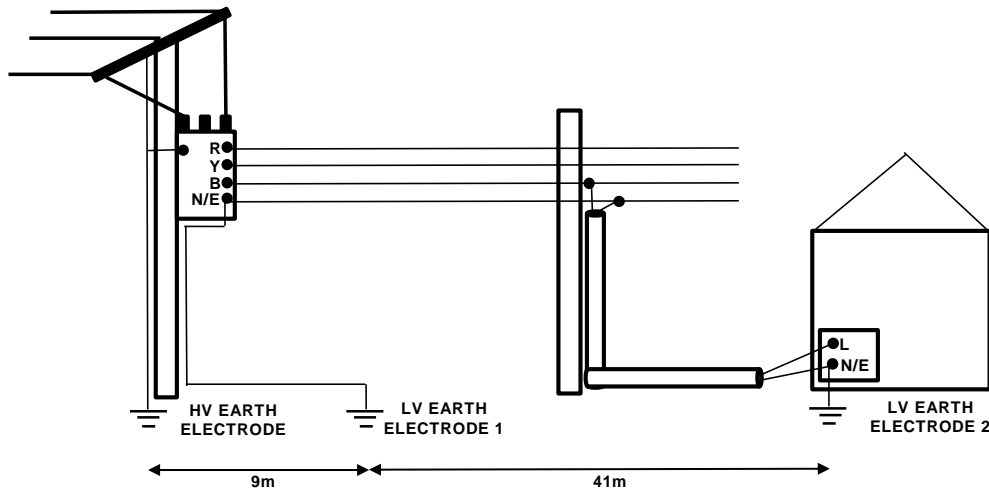

Figure 5.5 Example Pole-Mounted 11kV Substation Arrangement and LV Supply to a Dwelling

Using Formula R1 from Appendix B, the HV electrode earth resistance is calculated to be 21.5Ω. An earth fault current of 200A is assumed to flow and is assumed to be disconnected in 1s. The calculated EPR on the HV electrode is 4300V.

The Surface Potential 9m away from the HV electrode can be calculated using Equation P6.2 as 259V and would be experienced by LV Earth Electrode 1. In the absence of any additional LV earth electrodes this voltage would be propagated through the LV neutral/earth conductor and may be experienced as a Touch Voltage by the dwelling occupants. This potential exceeds the permissible Touch Voltage limit for 1s of 233V and so would not be acceptable.

Figure 5.5 shows a second LV electrode (LV Earth Electrode 2) located at the dwelling that is 50m away from the HV electrode. Use of Equation P6.2 provides a calculated Surface Potential of 48V that would be experienced by LV Earth Electrode 2.

Because LV Earth Electrodes 1 and 2 are connected via the LV neutral/earth conductor, and assuming they each have a similar earth resistance, the transfer potential on the LV earthing system (both electrodes and the interconnecting conductor) will be the average of the surface potential calculated at each LV electrode location, i.e. 154V which is below the permissible Touch Voltage limit.

If the resistance of LV Earth Electrode 2 was half that of LV Earth Electrode 1 the 'average' potential will be weighted more towards the potential at LV Electrode 2. From the equation in section 5.3.3(b), the combined potential on the LV earthing system would be (259x1 + 48x2)/3 = 118V.

This rather straightforward example illustrates how the electrode arrangement can be designed to significantly reduce the transfer potential.

574 Arrangement 2: 33/11kV Substation

575 A typical 33/11kV Substation earth electrode has been investigated in Case Study 1 and the
576 30m x 20m 'Basic Grid' had a calculated EPR of 1030V. A fault disconnection time of 0.6s is
577 assumed which has a corresponding permissible Touch Voltage of 420V.

578 For this case study it is assumed that the dwelling shown in Figure A5 is located 5m from the
579 33/11kV substation. Using Equation P6.3 the transferred potential to LV Earth Electrode 2 at
580 the dwelling, during a fault at the 33/11kV substation, is 477V. This is in excess of the
581 permissible Touch Voltage limit and may indicate an unacceptable risk to occupants of the
582 dwelling.

583 Using Equation P6.3 the transferred potential to LV Earth Electrode 1 (located 46m from the
584 33/11kV substation) can be calculated as 117V. Assuming that the two LV electrodes have a
585 similar earth resistance the average potential transferred to the LV earthing system during an
586 earth fault at the 33/11kV substation is 297V which is below the permissible limit.

587

588 **Risk assessment (No Section numbers as will move to 41-24)**

589 *This is just a brief introduction and needs further development. The whole of this*
590 *section will be placed in TS 41-24 eventually.*

591 It can be extremely expensive to control the risks of damage, shock or electrocution to levels
592 that are risk free. It is recognised in new standards that risks must be accepted in order to
593 provide electrical infrastructure to society. As set out in BS EN 50522, (BS EN 50522 : 2010 -
594 Earthing of power installations exceeding 1 kV a.c., 2010) risk assessment is one of the
595 acceptable tools for analysis of situations where the cost of removing an identified risk
596 appears to be disproportionately high.

597 When an earth fault creates a significant EPR within an installation, the following four
598 scenarios need to be considered:

599 **Injury or shock to persons within the installation**

600 At locations where a person is expected to be both working and in contact with earthed metal
601 (for example operating circuit breakers within a switchroom, a switching device in an outdoor
602 area or working on a power transformer), the earthing system must be designed to control
603 safety voltages such that they are below the acceptable threshold. The only unforeseeable
604 risks are associated with a defective earthing installation or failure of the protection
605 equipment. The design is expected to provide a high safety factor at such locations. For less
606 frequently occupied areas or intermittent tasks where the safety thresholds may be
607 exceeded, the risk should be managed by control measures (such as approved procedures,
608 permanent barriers and notices etc.) If these are still not initially deemed acceptable, the
609 decision on whether to carry out design improvements or accept the risk of an incident can be
610 aided by use of the risk assessment method described in BS EN 50522 A2. These examples
611 are presently quite simplistic and would need further development for widespread application.

612 **Injury or shock to persons and animals (if applicable) outside the installation**

613 These can be introduced by metallic transfer (fence, pipe, cable) or via the soil. Where a
614 transferred potential can occur due to metallically conductive means, that eventuality should
615 be removed by the introduction of insulation or other protective measures (examples include
616 insulated sections introduced into external metal fences.) Where metal fences are bonded to
617 the substation earthing system, the touch and step potentials external to them must be

618 controlled by the design, such that they are within the acceptable limits. In other words, most
619 risks should be managed by design. An ideal application for risk assessment is coated type
620 fencing (such as expanded metal) where parts of the coating may degrade over time. Where
621 HV and LV earthing systems are combined, the EPR is transferred from the installation into
622 domestic, commercial or industrial properties and must be at a level such that there is no risk.
623 *(We consider some research is needed to determine the threshold voltage for this from a*
624 *safety perspective (at present it is 430V – an ITU equipment limit value)).* Issues include
625 identification of the realistic shock scenarios in a range of property types and the probability
626 of this occurring and risking electrocution at a range of voltage levels. Where HV and LV
627 systems are combined, the EPR (or part of it) will transfer to the LV system.

628 For potentials transferred via the soil, the risk is related to the EPR magnitude (together with
629 proximity of the person, animal or property to the installation), the likely presence of humans
630 or animals and the degree/time of exposure. If the substation has an elevated EPR, obvious
631 concerns are shock risk to humans who do not have appropriate footwear (beach-side or
632 camping site locations) and electrocution to animals (such as a horse – especially one that is
633 being trained/ridden at the time).

634 Some guidance is needed for areas within the 430V contour – i.e. are there elevated risks or
635 is it an irrelevant contour in relation to human safety. The situation here is related to safe
636 touch and step potentials, not equipment thresholds. For example – risk of shock in a house
637 (similar scenario to the HV/LV bonded issue at a distribution substation), risk of shock in a
638 field, risk of shock to a horse whilst being ridden in an adjacent field.

639 **Damage to equipment within the installation**

640 This is generally covered by design practice and the need to meet the requirements of
641 documents such as EREC S36. For example, the use of isolation units of appropriate voltage
642 withstand on communication and protection circuits. It would be useful to have an element of
643 risk guidance in this area too – for example, if the isolation equipment is matched to normal
644 operating conditions, what is the risk of this being exceeded?

645 **Damage to equipment within properties outside the installation**

646 Communication equipment issues covered by EREC S36. (S36-1 : Identification and
647 Recording of Hot Sites - Joint Electricity / British Telecom Procedure, 2007)

648 Again – some of this is covered in EREC S36 – especially for telecommunication cables and
649 equipment. What is less obvious is the quantified risk of damage to non-communication
650 equipment or items that are not apparent from an initial survey. These may include metal gas
651 pipes, railway signalling, equipment within farm outbuildings etc.

652 **5.4   Risk assessment methodology**

653 For UK electricity industry applications, the risk of ventricular fibrillation (or electrocution) is a
654 function of three probabilities, i.e.:

655 P (Probability of ventricular fibrillation) = P_F x P_E x P_{FB}

656 Where

657 P_F : Probability of fault occurrence

658 P_E : Probability distribution of EPR value/Probability of exposure

659 P_{FB}: Probability of body orientation to create fibrillation current

660 ## 5.5 Methods of optimising the design (first draft)

661 Where the EPR is sufficient to create issues within or external to the substation, the following
662 should be investigated and the most practicable considered for implementation.

663 ### 5.5.1 More accurate evaluation of fault current

664 Does the value used, account for fault resistance and longitudinal circuit impedance? Have
665 excessive factors for future fault current growth been used? For example, it may be more
666 prudent to use the existing value and implement additional measures later, i.e. at the same
667 time as the predicted increase in fault current.

668 ### 5.5.2 Reducing the overall earth impedance

669 Can additional horizontal electrode be incorporated with new underground cable circuits?

670 Has the contribution of PILCSWA type cables in the vicinity been appropriately accounted
671 for?

672 **5.5.3 Reducing the touch potential within the installation**

673 Can rebar or other non-bonded buried metalwork be connected to the electrode system?

674 Can other measures (such as physical barriers or isolation) be applied to certain areas?

675 Are the areas of high touch potential actually accessible?

676

677 **6. Case study examples**

678 The four cases included here are to demonstrate the increasing level of complexity involved
679 when moving from an unearthed overhead supplied installation with a single supply through
680 to a distribution or transmission installation that has several sources of supply. These also
681 demonstrate the new design facilities that are expected at a modern installation, together with
682 use of the fault current analysis formulae available with this document.

683 The following data will be used for the first three case studies.

684 All electrodes assumed as having an equivalent circular diameter of 0.01m and for simplicity,
685 to be copper (the electrical properties of steel would be used for the reinforcing material.)

686 The soil resistivity is 75Ωm and the fault clearance time and fault current magnitude are set
687 out in Table 6.1.

688 Substation A

689 Earth resistance of 0.25Ω, obtained via a reliable measurement (see TS 41-24, Section 12
690 and BS EN 50522, National Annex C) Only part of the site is shown in the diagram – i.e. the
691 complete site encloses a larger area and this results in its low earth resistance.

692 The 33kV earth fault current at the source is limited to a maximum of 1kA by a neutral
693 earthing resistor. The fault current is further attenuated by the electrode resistance at the
694 faulted substation and the circuits' longitudinal impedance. In all cases the circuit is 3km long
695 between A and B and of 185mm^2 aluminum conductor. Tables 6.1 and 6.2 provide the fault
696 current data necessary to tie in withreferenced in the case study results.

Electrode (Fault) Resistance (Ω)	Fault Current (A)	Clearance Time (s)	Touch Voltage Limit (V) Inside Substation	Touch Voltage Limit (V) Outside Substation
0	610	0.4	944	837
0.25	595	0.4	944	837
0.675	584	0.4	944	837
1.22	565	0.4	944	837
1.42	560	0.4	944	837
1.59	555	0.4	944	837
1.89	545	0.4	944	837
2.0	525	0.4	944	837

697 **Table 6.1 Fault current versus case study substation earth resistance – overhead line
698 Substation B (cable and overhead line circuit)**

Commented [DC17]: Where is the fault position? Needs explaining

Commented [DC18]: Remove, include relevant data in each case study

Commented [DC19]: General table - Remove general table and just have the case studies with a relevant table included in each

Commented [DC20]: Check with 41-24, also inside the substation are there chippings and at what level. Insert into heading what it is.

699

Electrode (Fault) Resistance (Ω)	Fault Current (A)	Clearance Time (s)	Touch Voltage Limit (V) Inside Substation	Touch Voltage Limit (V) Outside Substation
0 to 2	820	0.4	944	837

Commented [DC21]: Is the 820 related to zero ohms?

700 **Table 6.2 Fault current versus substation earth resistance (all cable circuit)**

Commented [DC22]: Shift this table to Case Study 2

701 Substation B

702 The grid is 30m long, 20m wide and will be buried 0.6m deep.

703 **6.1. Case Study 1 Overhead line fed 33kV substation**

704 A new 33kV substation is being built at location B. It is supplied from substation A via an
705 unearthed, wood pole supported line that terminates just outside the operational boundary of
706 each substation. The substations are assumed to consist of just three items of plant, (HV and
707 LV switchgear and a power transformer), each on their own individual foundation slab. This
708 is the most straightforward example to study and will be used to demonstrate both the
709 modern design approach and methods of addressing touch potentials.

710 The approach used can be applied to similar arrangements at a range of voltage levels from
711 6.6kV to 66kV. At 6.6kV and 11kV, the substation would generally occupy a smaller area
712 than in the examples shown.

713
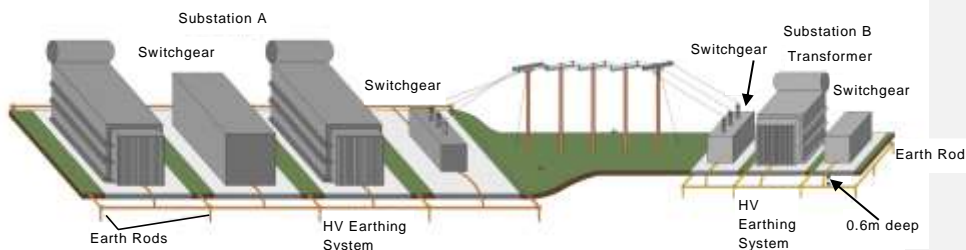

714 **Figure 6.1 Supply arrangement for case study 1**
715 **(Overhead line fed substation)**

716 **6.1.1 Resistance calculations**

717 For this case, the land area is assumed to be fixed. The first calculation assumes a minimum
718 earthing system consisting of a perimeter electrode between 0.5m outside the foundation
719 slabs and two cross members in-between the slabs (Fig.6.2.) For the next iterations, ten
720 vertical 3.6m rods are added (Fig.6.3) and then some horizontal rebar within each foundation
721 slab (Fig.6.4.)
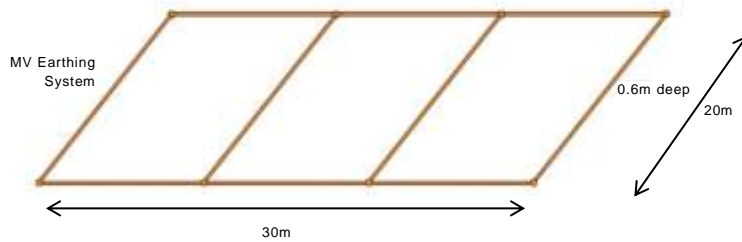

722 **Figure 6.2 Substation B basic earth grid**

723 Using Formula R4 from Appendix B, as below:

725 $R_E = \dfrac{\rho}{4r} + \dfrac{\rho}{L}$

724

726 Where $L =$ length of buried conductor;

727 $r = \sqrt{\dfrac{A}{\pi}}$

728 $A =$ area of grid.

729 Substituting the values, as below:

730 $R_E = \dfrac{75}{4r} + \dfrac{75}{140}$

731 Where

732 $r = \sqrt{\dfrac{A}{\pi}} = \sqrt{\dfrac{600}{\pi}} = 13.8$

733 $R_E = \dfrac{75}{55.2} + \dfrac{75}{140}$

734 $R_E = 1.89\Omega$

735 Adding the ten rods as below, each of 3.6m length and 16mm radius, requires the use of the
736 more detailed formula.

MV Earthing System

0.6m deep

Earth Rods
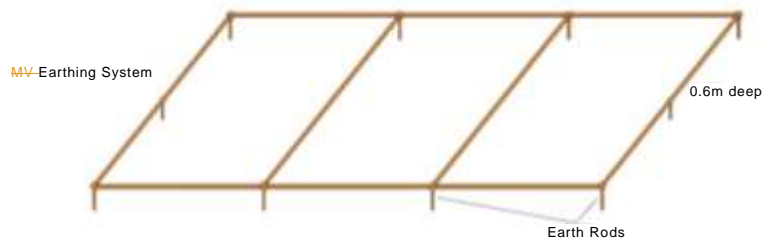

737 **Figure 6.3 Substation B basic earth grid and rods**

738
739 Using Formula R6 from Appendix B:

741 $$R_E = \frac{R_1 R_2 - R_{12}^2}{R_1 + R_2 - 2R_{12}}$$

740

742 Where:

$$R_1 = \frac{\rho}{4r} + \frac{\rho}{L}$$

$$R_2 = \frac{R'}{N}(1 + k\alpha)$$

L = length of buried conductor (176m);

$$r = \sqrt{\frac{A}{\pi}}$$

$$R' = \frac{\rho}{2\pi l}\left(log_e \frac{8l}{d} - 1\right)$$

A = area of grid (m²)

N = number of rods = 10

r_h = Radius of equiv. hemisphere for 1 rod

$$R_{12} = R_1 - \frac{\rho}{\pi L}\left(log_e \frac{l}{b} - 1\right)$$

$$r_h = \frac{\rho}{2\pi \times R'}$$

Where b is the equivalent diameter of the circular earth electrode or the width of a tape electrode.

l and d are the rod length and diameter

a is the separation between rods

$$\alpha = \frac{r_h}{a}$$

k = factor, which is 5 for 10 rods – see Appendix 2, formula R5

$$\alpha = \frac{r_h}{a} = \frac{0.55}{10} = 0.055$$

$$R' = \frac{75}{2\pi \times 3.6}(log_e(\frac{8 \times 3.6}{0.016}) - 1) = 21.6\Omega$$

Therefore;

$$R_1 = \frac{75}{4 \times 13.82} + \frac{75}{176} = 1.78\Omega$$

$$R_{12} = 1.78 - \frac{75}{\pi \times 176}\left(log_e \frac{3.6}{0.01} - 1\right) = 1.12\Omega$$

$$R_2 = \frac{21.6}{10} \times (1 + 4.9 \times 0.06) = 2.7\Omega$$

$$R_E = \frac{1.78 \times 2.7 - 1.12^2}{1.78 + 2.7 - 2 \times 1.12} = 1.6\Omega$$

743 As can be seen, the rods have reduced the resistance to 1.6 ohms~~slightly~~ from the previous
744 calculated resistance of 1.89Ω.

745 For the final calculation, the rebar within the horizontal foundations have been approximated
746 by the symmetrical meshes shown in Figure 6.4. For simplicity it is assumed that they have
747 the same equivalent circular diameter as the copper conductor and the same electrical
748 properties (Note 1)
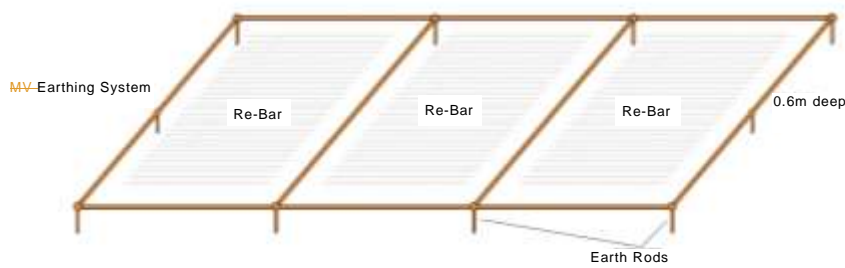

749 **Figure 6.4 Substation B earth grid with rods and rebar**

750 The same formula (R6) and approach would be used as previously, except that the length of
751 conductor is increased to include the amount of rebar modelled (786m total of rebar added to
752 that of copper).

753 Using Formula R6 from Appendix B:

754
$$R_E = \frac{R_1 R_2 - R_{12}^{\ 2}}{R_1 + R_2 - 2R_{12}}$$

755 Where:

$$R_1 = \frac{\rho}{4r} + \frac{\rho}{L} \qquad\qquad R_2 = \frac{R'}{N}(1 + k\alpha)$$

$$R_1 = \frac{75}{4 \times 13.82} + \frac{75}{962} = 1.45\Omega \qquad\qquad \alpha = \frac{r_h}{a} = \frac{0.55}{10} = 0.055$$

$$R_{12} = 1.45 - \frac{75}{\pi \times 962}\left(log_e \frac{3.6}{0.01} - 1\right) = 1.3\Omega \qquad R' = \frac{75}{2\pi \times 3.6}(log_e\left(\frac{8 \times 3.6}{0.016}\right) - 1) = 21.6\Omega$$

$$R_2 = \frac{21.6}{10} \times (1 + 4.9 \times 0.055) = 2.7\Omega$$

756
$$R_E = \frac{1.45 \times 2.7 - 1.3^2}{1.45 + 2.7 - 2 \times 1.3} = 1.42\Omega$$

757 This provides a slightly lower resistance of 1.42Ω.

758 Note 1: For a more detailed analysis, the equivalent diameter of the different electrodes and their electrical properties and
759 orientation would be included. In the majority of cases, this would require the use of a computer simulation package. When
760 used, the resistance of the grid in Figure 6.4 falls to 1.22Ω.

761 **6.1.2 Calculation of EPR**

762 For each of the grid arrangements modelled, their resistance would be included in the fault
763 current flow calculation to determine the likely earth fault current, as detailed in Table 6.2.

Arrangement	Resistance (Ω)	Attenuated Fault Current (A)	EPR (V)
Basic grid	1.89	545	1030
Grid & rods	1.59	555	888
Grid, rods & rebar (using formula)	1.42	560	796
Grid, rods & rebar (using computer software)	1.22	565	695

764 **Table 6.3 EPR for different grid arrangements**

765 As can be seen from Table 6.3, addition of the rods and rebar have each reduced the
766 resistance and EPR, but not dramatically. The site has an EPR that exceeds the present
767 430V elevated EPR threshold and it is necessary to calculate the external impact, i.e., the
768 430V contour location etc. Similarly, if the EPR is greater than the acceptable step/touch
769 limit, it is necessary to calculate the safety voltages. For all subsequent calculations, the
770 resistance of 1.42Ω will be used.

771 **6.1.3 Calculation of external voltage impact contours**

772 This requires use of Formula P6.3 from Appendix B (Note that calculations are in radians).
773 Formula P6.3 can be more usefully rearranged to provide the distance from the outer edge of
774 the earth grid to a set potential point in relation to the EPR that has already been calculated.

775 The procedure to determine the distance to the 430V contour is as below:

776 $$Z_{430} = \sqrt{\frac{A}{\pi} \left[\left(sin \frac{430 \times \pi}{2\text{EPR}} \right)^{-1} - 1 \right]}$$

777 Substituting the values for A (600m[2]) and the EPR (796V), provides a distance Z of 5m.

778 $$Z_{430} = \sqrt{\frac{600}{\pi} \left[\left(sin \frac{430 \times \pi}{2 \times 796} \right)^{-1} - 1 \right]} = 5m$$

779 Similar calculations would be carried out for other contours of interest. It is important to note
780 that these calculations only apply with a reasonable degree of accuracy to a grid that is close
781 to a square shape and in uniform soil. For irregular shaped grids, such as one with radial
782 spurs, a computer simulation or actual site measurement is necessary for sufficient accuracy.

783

784 **6.1.4 Calculation of touch potentials**

785 These calculations are included for reference purposes, but would not be needed in real
786 studies because the EPR is less than 2 x U_{TP} (the permissible touch voltage of 837V to 944V
787 as shown in table 6.1.) Formula P1 estimates the touch potential one metre beyond the
788 perimeter electrode. It is usually the case that provided the internal electrode has been
789 correctly designed (with sufficient meshes), the touch potential here will exceed that
790 anywhere within the grid area. For unusually shaped or non-symmetrical grids, computer
791 software tools are needed for an accurate calculation.

> **Commented [DC23]:** Re-do study with different values of earth resistance/fault current so it is needed

792 The calculation procedure is as below:

793 For simplicity, the grid without foundation rebar is used, as in Figure 6.3. A single cross
794 member is added later to give an initial estimate of the effect of the rebar.

795 **6.1.4.1 External touch potential at the edge of the electrode**

796

797 $$E_{t(grid)} = \frac{k_e \cdot k_d \cdot \rho \cdot I}{L}$$

798

799 $$k_e = \frac{1}{\pi}\left(\frac{1}{2}log_e\frac{h}{d} + \frac{1}{2h} + \frac{1}{(0.5+d)} + \frac{1}{D}(1 - 0.5^{n-2})\right)$$

800 $h = 0.6$m, $d = 0.01$m,

801 D = average spacing between parallel grid conductors - 20metres

> **Commented [DC24]:** Check throughout – m not metres etc

802 $n = (n_A \times n_B)^{1/2}$

803 Where $n_A = 2$, $n_B = 4$

804 k_d is a factor which modifies k_e to allow for non-uniform distribution of electrode current and
805 is given by:

806 $$k_d = \left(0.7 + 0.3\frac{L}{L_p}\right)$$

807 Where L = total length of buried electrode conductor including rods if connected (176 m
808 metres)

809   L_p = length of perimeter conductor including rods if connected (136 m metres)

810     $\rho = 75\Omega$m

811   I = total current passing to ground through electrode (555 A amperes)

812 $U_{T(grid)} = 248.2$V

813 This reduces to 224.7V when the additional central cross member along the x axis is added
814 (this adds 30m of electrode and provides a uniform separation between mesh conductors in
815 each direction of 10m).

816

817 For the case where there are more cross members or to account for the rebar, the additional
818 conductors are accounted for in the formula in a similar process to that above and will
819 provide a lower touch potential.

820 For comparison purposes, when the grids are modeled using computer software, the touch
821 potentials (based upon the computer calculated EPR of 695V) are:

822 • Basic grid (plus rods), touch voltage maximum is 35% on the edge of the grid and 29%
823   inside (311V or 258V.).

824 • With rebar included, touch voltage maximum is 28% on the edge of the grid and only 5%
825   inside (195V or 35V.).

826 These are all significantly lower than the touch voltage limit of 944V (Table 6.21.) Since the
827 EPR exceeds the TS 41-24 "hot" threshold, the site's HV and LV earths would need to be
828 separate.

829 For comparison purposes, when the grids are modelled using computer software and with
830 the rebar included, the EPR is 695V, so the touch voltage maximum is 195V (28%) on the
831 edge of the grid and just 35V (5%) inside, demonstrating the contribution towards safety that
832 the rebar provides.

833 For the case where there are more grid cross members or to include the rebar, the additional
834 conductors are accounted for in the formula in a similar process to that above and will
835 provide a lower touch potential.

836 **6.1.4.2 Touch potential on fence**

837 If a metal fence is present about 2m outside the electrode system, independently earthed in
838 accordance with TS 41-24, then by substituting the variables into Appendix B Formula P2,
839 the touch voltage 1m external to the fence can be calculated and is 58V.

840

841 **6.2 Case study 2**

842 In this example, the data is identical except that the circuit between the substations is 3km of
843 185mm^2 aluminium triplex type cable, where each cable has a 35mm^2 stranded copper
844 screen.

845
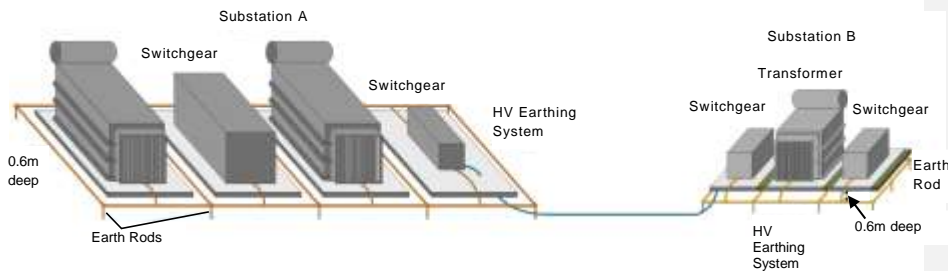

846 **Figure 6.5 Supply arrangement for case study 2**

847 The resistance calculations are identical to those completed for case study 1 and the initial
848 analysis will focus on the values that include the rebar and vertical earth rods (1.22Ω
849 computed using software.) R_A is 0.25Ω. Because the all cable circuit has a lower
850 longitudinal phase impedance compared to a cable and overhead line one, the earth fault
851 current at B is 820A and the other data is as shown in table 6.2.

852 The results shown in Ttable 6.4 have been obtained using the appropriate formula and the
853 cable data from Appendix D, table 1.

Component	Value
R_A	0.25Ω
R_B	1.22Ω
L	3km
I_F	820A
I_{ES}	17.64%
I_{ES}	144.7A
EPR$_B$	176.5V

854 ~~Table 6.4~~Table 6.4 **Case study 2, input data and results**

855 The amount of earth fault current that returns via the cable sheaths is so significant (more
856 than 82%) that the current flowing through the 1.22Ω substation resistance creates an EPR
857 of only 176V, despite the higher overall fault current. At this level, the EPR is lower than the
858 430V threshold (creating a "cold" site) and lower than the touch voltage limit, so no further
859 calculations are necessary. Sensitivity studies showed that the earth resistance at B could
860 increase to more than 20Ω and the EPR would still be significantly lower than 430V. This
861 means that the need for the earth rods will be based more upon seasonal effects (such as
862 reliability of soil water content over the year) than a need to reduce the grid resistance.

863 The worst conceivable situation would involve the loss of the sheath connections co-incident
864 with the earth fault. This is considered an unlikely event especially for the triplex (three cable)
865 type circuit. The EPR would increase to about 1000V (1.22Ω x 820A). However the
866 foundation rebar and perimeter electrode would restrict the touch voltage to just 5%, i.e. 50V,
867 which is much lower than the limit threshold of 944V. So the site would still be "'safe",

Commented [DC25]: Not consistent with 1.4 ohms

Commented [DC26]: Include Table 6.2 in this section

Commented [DC27]: Could include calculation if not too long

Commented [DC28]: Remove references to hot and cold sites and ref to 430V

868 although there would now be an external zone in which the surface potential would exceed
869 430V.

870 The equations in Appendix D have been used to derive the results used, with the relevant
871 cable self and mutual impedances.

872 (NOTE: that it is considered improbable that all the current could return via the electrode as this would require all
873 three individual cable screens to be open circuit con-incident with the fault.)

874

875 **6.3 Case study 3**

876
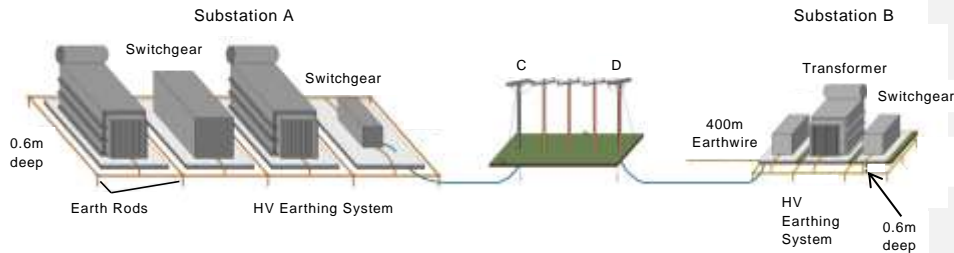

877 **Figure 6.6 Supply arrangement for case study 3**

878 This is a more complex example to demonstrate the issues involved in an area where there
879 are towns or villages supplied from an overhead line network. This is a very common
880 arrangement at 11kV and the same procedure is used to analyse that, but using the 11kV
881 fault current routines and associated data rather than the 33kV ones used here.

882 The circuit length remains at 3km, with 500m of cable at each end and 2km of overhead line
883 in the centre. The terminal poles at C and D will have their own independent electrodes (rods
884 and/or buried earth wire) to achieve a resistance of 10Ω for insulation co-ordination
885 purposes.

886 The resistance of substation B is the same as calculated previously. However, as is
887 common practice, the opportunity has been taken to install some earth wire with the
888 incoming cable that is connected to the earth grid. A length of 150m is assumed and this will
889 have a resistance that will act in parallel with that of the grid.

890 If modelled in computer software, the combined resistance is 0.675Ω and this accounts for
891 proximity effects.

892 If software is not available, the calculation can be carried out as follows:

893 Resistance of radial earth wire

894 Using formula R7 from Appendix B, as below:

895 $$R_H = \frac{\rho}{2\pi L}\left[log_e\left(\frac{L^2}{1.85hd}\right)\right]$$

896 The resistance of the earth wire is 1.46Ω (using the J. Endrenyi approach based on a ladder
897 network with distributed parameters.) (Endrenyi, J : Reliability Modelling in Electric Power
898 Systems, 1979). The resistance of the earth grid is 1.22 Ω. In parallel, the combined
899 resistance (ignoring proximity effects) is:

900 1.46Ω // 1.22Ω = 0.665Ω

901 When proximity effects are included, by using a computer design package, the calculated
902 resistance value increases only slightly to 0.675Ω. The corresponding earth fault current
903 (Table 6.1) is now 584A. These values will be used for the subsequent calculations.

904 As in case study 2, the formula of Appendix D and cable data in Appendix D, table 1 are
905 used to calculate the fault current distribution.

Commented [DC30]: Make clear where the fault is located (Substation B)

Commented [DC31]: Move to bibliography

Component	Value
R_D	10Ω
R_B	0.675Ω
L	1km
I_F	584A
I_{ES}	93.6%
I_{ES}	546.6A
EPR$_B$	369V

906 **Table 6.5 Case study 3, input data and results for end part of circuit**
907 (Note that R$_A$ is used in formula to represent R$_D$)

> **Commented [DC32]:** Should this be the other way around?

908 As can be seen in Table 6.5, almost all of the fault current (about 94%) flows through R_B and
909 creates an EPR of 369V. The amount of copper conductor laid with the cable is sufficient to
910 provide an EPR of less than 430V. Further optimization could be carried out to reduce the
911 length of copper conductor used whilst still achieving an EPR of <430V.

> **Commented [DC33]:** Do we need to ref 430V
>
> **Commented [DC34]:** Do we need to ref 430V

912 Note that the small amount of current (6.4%) that flows via the cable sheaths and through R_D
913 into the soil, will create an EPR of approximately 374V there.

Component	Value
R_C	10Ω
R_A	0.25Ω
L	1km
I_F	584A
I_{ES}	97.4%
I_{ES}	569A
EPR$_A$	142V

914 **Table 6.6 Case study 3, input data and results for start part of circuit**
915 (Note that R_B is used in the formula to represent R_C)

916 The same equation can be used to predict the EPR at the source substation and the first
917 pole/cable interface at C.

918 As can be seen from Table 6.6, the EPR at point A is only 142V, due to the lower earth
919 resistance there.

920 The EPR at locations A and B are sufficiently low that calculation of touch, step and external
921 impact contours are not required.

6.4   Case study 4

6.4.1 Introduction

In UK transmission networks (generally operating at voltages of 132kV and above) the System Neutral is solidly and multiply earthed. This is achieved by providing a low impedance connection between the star point of each EHV transformer (primary) winding and each substation earth electrode. The low impedance neutral connection often provides a parallel path for earth fault current to flow and this reduces the amount of current flowing into the substation earth electrode. For EPR calculations in such systems, the neutral returning component of earth fault current must be considered. The current "split" between the different return paths in this study is shown by red arrows in Figure 6.7 below.

Circuits entering a substation are often via a mixture of overhead and underground cables. As explained in Section 4, a high percentage of the earth fault current flowing in an underground cable circuit will return to source via the cable sheath if bonded at both ends (typically 70% to 95%), whereas in an earthed overhead line circuit the current flowing back via the aerial earthwire is a lower percentage (typically 30% - 40%). It is therefore necessary to apply different reduction factors to the individual currents flowing in each circuit. The individual phase currents on each circuit are required for these calculations.to calculate these factors.

The detailed fault current data required is normally available at transmission level from most network modelling software packages. Any additional calculation effort at an early stage is usually justified by subsequent savings in design and installation costs that result from a lower calculated EPR.

This case study has been selected to illustrate:

 a)   Calculations to subtract the local neutral current in multiply earthed systems;

 b)   The application of different reduction factors for overhead line and underground cable circuits;

 c)   A situation where there are fault infeeds from two different sources

6.4.2 Case Study Arrangement

Figure 6.7 shows a simplified line-diagram of an arrangement where a 132kV single phase to earth fault is assumed at 132/33kV Substation X. Two 132kV circuits are connected to Substation X, the first is via an overhead line from a 400/132kV Substation Y and the second is via an underground cable from a further 132/33kV Substation Z which is a wind farm connection. There is a single transformer at Substation X and its primary winding is shown together with the star point connection to earth.

982

983 **6.4.3 Case study data**

984 For the single phase to earth fault on Phase A illustrated in Figure 6.7, the individual currents
985 flowing on each phase of each circuit and in the transformer HV winding are shown in Table
986 6.7. This data is typical of that from short-circuit software package used for transmission
987 studies.

988 **Table 6.7 Case study short-circuit data**

989 **6.4.4 Treatment of neutral current**

990 In Table 6.7 the 'Sum of contributions into Substation X' is the vector sum of the faulted 'A'
991 Phase contributions from the two lines and the transformer and is defined as the Total Earth
992 Fault Current (I_F). The contribution shown as 'Transformer (HV Side)' represents the
993 transformer star-point or 'neutral' current (I_N).

994 The current that returns to Substations Y and Z via Substation X Earth Electrode (I_{ES}) is
995 separate from that flowing back via the transformer neutral (I_N) and metallic paths (neutral
996 and healthy phases). It can be shown that $I_F - I_N = 3I_0$ where $3I_0$ is the three times the sum
997 of zero-sequence current on all lines connected to the substation. For each line, $3I_0$ is equal
998 to the vector sum of the individual line phase currents, i.e. $3I_0 = I_A + I_B + I_C$.

999 Table 6.8 provides the calculated $3I_0$ values for each of the two lines and their sum.

Contribution fFrom:	$3I_0$ Magnitude (kA)	$3I_0$ Angle (Deg)
Substation Y	2.916	76.9
Substation Z	8.559	74.8
Sum of Contributions from Y+Z	11.470	75.3

1000 ~~Table 6.8~~Table 6.8 **Total three times zero sequence current ($3I_O$)**

> **Commented [RW35]:** TEC: Title needs changing

1001 From Tables 6.7 and 6.8 it can be seen that earth fault current magnitude of 13.07kA (as
1002 indicated by the short-circuit package) reduces to 11.47kA once the local neutral current is
1003 subtracted.

1004 As a further check of this value the sum of the currents flowing on the Transformer (HV Side)
1005 can be subtracted from the total earth fault current from the short-circuit package to arrive at
1006 the same result, i.e. $13.07\angle74° - 1.62\angle65.3° = 11.47\angle75.3°$ (kA)

1007 **6.4.5 Fault current distribution**

1008 The circuit from Substation Y is via an overhead line whereas that from Substation Z is via an
1009 underground cable. Further calculations are required to calculate the fault current distribution
1010 between the substation electrode, tower line earthwire and the underground cable sheaths.

1011 Table 6.9 lists the additional information assumed for this case study.

Line construction between Substations X and Y	132kV double circuit tower line – L4 construction. 20 spans long.
Reduction factor for line between Substations X and Y	0.708∠-9° (as per EREC S.34, Appendix E)
Line construction between Substations X and Z	132kV, 3 x 1c, 300mm^2 aluminium conductor, 135mm^2 copper-wire screen, XLPE insulated. 5km circuit length.
Substation Y Earth Resistance	0.1Ω
Substation X Earth Resistance	0.5Ω
Reduction factor for line between Substations X and Z	0.067∠178°

1012   **Table 6.9 Case study information for fault current distribution calculations**

1013   The calculated reduction factors (r_E) for each circuit type from Table 6.9 are applied to the
1014   three-times zero-sequence currents ($3I_0$) on each circuit and the total ground return current
1015   (I_E) calculated as shown in Table 6.10.

Contribution From:	$3I_0$ Magnitude (kA)	$3I_0$ Angle (Deg)	r Magnitude	r Angle (Deg)	I_E Magnitude (kA)	I_E Angle (Deg)
Substation Y	2.916	76.9	0.708	-9	2.06	67.9
Substation Z	8.559	74.8	0.067	178	0.565	252.8
Sum of Contributions from Y+Z	11.470	75.3			1.50	66.1

1016   **Table 6.10 Calculated ground return current**

1017   The total Ground Return Current magnitude (I_E) is shown to be only 1.5kA which is
1018   significantly lower than the short-circuit current at the fault point (I_F) of 13.07kA.

1019   **6.4.6 Earth potential rise**

1020   The Earth Potential Rise (EPR) can be calculated simply as the product of the Ground
1021   Return Current I_E and the overall Earth Resistance R_E at Substation X, i.e. 1.5kA x 0.5Ω =
1022   750V

1023

1024   **APPENDICES**

1035 **APPENDIX A – Symbols used within formulae**

1036 *(Those shown in <u>Old</u> column were used in earlier versions of this document, but have been updated to align*
1037 *with BS EN 50522:2010*

1038 System components

New	*Old*	Symbol Description
CH	*CH*	chain (or ladder) network of an overhead line earthwire with its connections to earth via metal lattice towers along its route, or an insulated cable's sheath that has connections to earth via installations along its length
FT	*FT*	fault-throwing switch
EG	*G*	installation's grid electrode
h	*H*	external horizontal electrode (e.g. a copper tape, un-insulated stranded copper conductor or a power cable with no insulated serving – i.e. PILC or PILCSWA – that is laid direct in the soil)
E_P	*P*	plate electrode
E_R	*R*	rod electrode
s	*S*	line earthwire
E_T	*T*	line tower footing electrode

Electrical quantities and dimensions

I_F	I_F	total earth fault current – A
I_{ES}	I_E	component of I_F passing to ground through grid electrode – A
I_E	I_{gr}	component of I_F that flows through the electrode network and eventually all returning through the ground – A
rE	I_E	reduction factor of the overhead line
I_N	I_l	current via local transformer neutral - A
I_r	I_r	component of I_F through remote transformer neutrals – A
I_h	I_h	component of I_E passing to ground through external horizontal electrode – A
I_S	I_{Sr}	component of I_F returning through earthwire or cable sheath – A
I_{ET}	I_t	component of I_E passing to ground through tower footing – A
k	*k*	screening factor of conductors carrying induced current – e.g. earth-wires, cable sheaths
Z_x		distance to point where voltage on soil is x∨¥ – m
D	*D*	average spacing between parallel grid electrodes – m

Commented [DC36]: E should be a subscript

Formatted: Font: Not Italic

Formatted: Font: Not Italic

New	Old	Symbol Description
d	d	diameter or circular electrode or width of tape electrode – m
L	l	cable length – km
L_R	l_R	length of earth rod - m
L_E	l_E	total length of electrode (e.g. in grid) - m
L_H	l_H	horizontal electrode length - m
L_p	l_P	grid or loop electrode length - m
ρ	p	earth resistivity – Ωm
r_a	r_a	cable armour resistance – Ωkm
r_c	r_c	cable sheath resistance – Ωkm
h	h	radius of equivalent hemisphere – m
R_R		resistance of single rod – Ω
R_{ER}	R_2	resistance of group of rods – Ω
R_A		earthing resistance at substation A - Ω
R_B		earthing resistance at substation B - Ω
R_E	R_e	total earthing resistance at substation – Ω
R_F	R_f	fault resistance – Ω
R_{ES}	R_l and R_g	grid electrode earthing resistance – Ω
R_{EH}	R_h	external horizontal electrode earthing resistance - Ω
R_{NE}	R_{ne}	neutral earthing resistance - Ω
R_{EP}	R_p	earth plate resistance – Ω
R_{ET}	R_t	tower footing resistance - Ω
s	S	line span length – km
U_E	V_e	rise of earth potential of substation – V
U_T		touch potential – V
U_S		step potential – V

Commented [DC37]: All definition of Ls need to be looked at

New	*Old*	**Symbol Description**
U_{VT}		prospective touch potential – V
U_{VS}		prospective step potential – V
U_{SP}		permissible step voltage – V
U_{TP}		permissible touch voltage – V
φ		earth surface potential
V_S	V_S	voltage on the surface of the soil at point s, with respect to true earth potential – V
Z_Q		tower line earthwire impedance per km - Ω
Z_C	z_c	cable sheath impedance This is the overall sheath and armour of 3-core cables or sheaths of 3 × single-core cables – Ωkm
Z_{CH}	Z_{ch}	chain (or ladder) network impedance – Ω (Referred to as Z_p in BS EN 60909-3:2010)
Z_e		substation earthing impedance – Ω
Z_E		impedance to earth
Z_∞		chain impedance (earth wire/tower footing) of the overhead line assumed to be infinite
$z_{mp,1}$	$z_{mp,1}$	mutual impedance between cable conductor and sheaths 1, 2 and 3 respectively
$z_{mp,2}$	$z_{mp,2}$	of three single core cables - Ωkm
$z_{mp,3}$	$z_{mp,3}$	
$z_{ml,2}$	$z_{mp,2}$	mutual impedance between sheaths 1, 2 and 3 of three single core cables - Ωkm
$z_{ml,3}$	$z_{mp,3}$	
$z_{m2,3}$	$z_{mp,3}$	
$z_{mp,s}$	$z_{mp,s}$	mutual impedance between line conductor and earthwire - Ωkm
$z_{mp,c}$	$z_{mp,c}$	mutual impedance between cable conductor and sheath of three core cables - Ωkm
Z_S		earthwire impedance - Ωkm
$\angle$	$\angle$	angle in degrees

1040 **APPENDIX B – Formulae**

1041 Earth resistance formulae. (Note that all formulae are those from EREC S34, 1986 version,
1042 except where noted otherwise).

1043 Symbols are defined in Appendix A unless specifically defined in this Appendix.

1044 Refer to (BS 7430)(BS 7430, 2012) for additional formula related to simple rod arrangements
1045 that would not generally be used at distribution or power company installations.

1046 The formulae have been grouped as follows:-

1047 **R = earth resistance of different arrangements**

1048 **C = current rating**

1049 **P = potentials (surface, touch and step)**

1050 **Formula R1 Rod electrode**

$$R_{ER} = \frac{\rho}{2\pi L_R}\left[log_e\left(\frac{8L_R}{d}\right) - 1\right]$$

1051 **Formula R2 Plate electrode (mainly used for sheet steel foundations)**

$$R_{EP} = \frac{\rho}{8r}\left(1 + \frac{r}{2.5h + r}\right)$$

where:

$$r = \sqrt{\frac{A}{\pi}}$$

1052 $A =$ area, $h =$ depth

1053 **Formula R3 Ring electrode**

$$R_E = \frac{\rho}{4\pi^2 r}\left(log_e\frac{64r^2}{dh}\right)$$

where:

$h =$ depth (m)

$r =$ ring radius (m) $= \sqrt{\frac{A}{\pi}}$

$d =$ conductor diameter (m)

1054 **Formula R4 Grid/mesh resistance**

$$R_{ES} = \frac{\rho}{4r} + \frac{\rho}{L_E}$$

1055 **Formula R5 Group of rods around periphery of grid**

$$R_{ER} = \frac{\rho}{N2\pi L_H}\left(log_e\frac{8L_h}{d} - 1\right)(1 + k\alpha)$$

α = Radius of equivalent hemisphere for 1 rod = $\frac{\rho}{2\pi R}$ (metres)
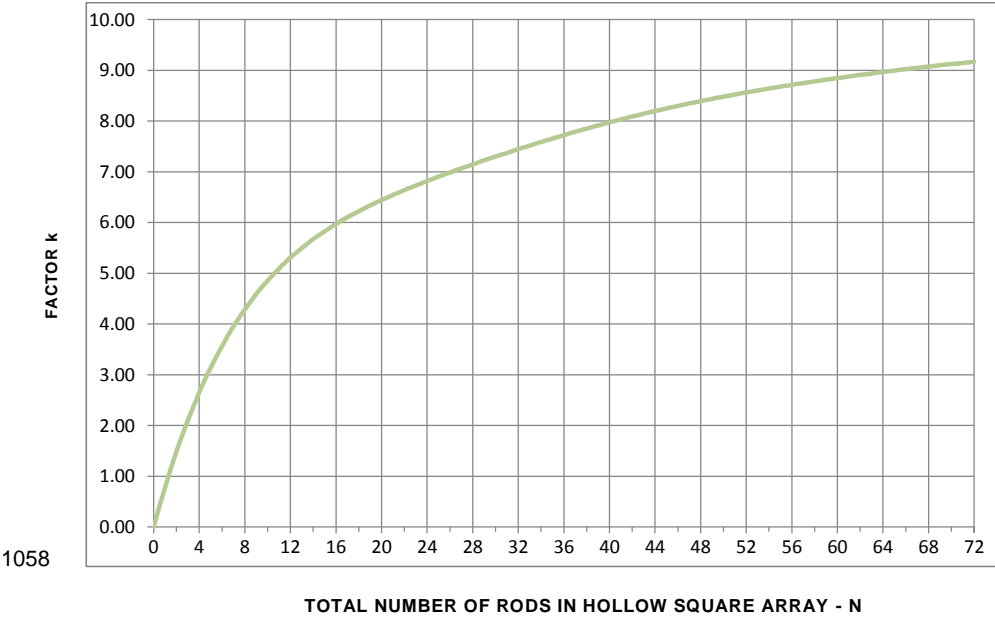

k=factor from figure below:

N: total number of rods around periphery of grid

1056

1057   **K factor for formula R5**

TOTAL NUMBER OF RODS IN HOLLOW SQUARE ARRAY - N

1058

Formula R6 Combined grid and rods (rods on outside only)

$$R_{ES} = \frac{R_1 R_2 - R_{12}{}^2}{R_1 + R_2 - 2R_{12}}$$

where:

R_1 = resistance of grid (Formula R4)

R_2 = resistance of rods $\frac{R'}{N}(1 + k\alpha)$ (Formula R5)

$$R_{12} = R_1 - \frac{\rho}{\pi L}\left(log_e \frac{l}{b} - 1\right)$$

$b = w/\pi$

where w = width of tape electrode (m), L = length of buried conductor (m), l = rod length (m)

Note : the formula only provides sensible results for generally used dimensions – in particular for normal or rod widths/diameters.

Formula R7 Strip/tape electrode

(BS 7430)(BS 7430, 2012) – *See* Appendix F or use the formula:

$$R_H = \frac{\rho}{2\pi L_H}\left[log_e\left(\frac{L_H{}^2}{1.35 hd \; x \; (burial \; depth - m)}\right)\right]$$

The above formula is only valid up to certain lengths (the effective length) which is typically about 300m for average soil and substation applications, after which the effect of adding further length is significantly diminished due to the self impedance of the electrode that is not accounted for in Formula R7. The approximate effective lengths for a single earthwire, tape or PILCSWA cable are shown in Table 1 below. For larger cables – in particular where there are several in reasonably close proximity, computer software or a more detailed equation (such as Schwartz – IEEE80 section 14.3) should be used. The advantage of using computer software is that the extended electrode cross sectional area and material can be correctly accounted for.

See also Formula R9 and Table 2 for estimates of proximity factors when electrodes are run in parallel.	
Soil Resistivity p	Effective Length m
1	60
10	180
100	500
1000	1500

Table A2.1 Approximate effective lengths for a single earthwire, tape or PILCSWA cable

Formula R8 Ladder networks

Long circuits. In all cases, quantities are impedances, not magnitudes.

R8.1 – Long overhead lines with earthwire (BS EN 60909-3, 2010)

$$Z_{CH} = 0.5Z_Q + \sqrt{(0.5Z_Q)^2 + R_{ET} \cdot Z_Q}$$

See (BS EN 60909-3, 2010) for description of Z_Q. Appendix G provides calculated values of Z_{CH} for a traditional UK 132kV tower line.

R8.2 – Long cable circuit with distributed earthed nodes (distribution substation electrodes) (BS EN 60909-3, 2010)

$$Z_{CH} = \frac{Z_1 + \sqrt{Z_1{}^2 + 4 \cdot Z_1 \cdot Z_2}}{2}$$

Where Z_1 = average longitudinal sheath impedance of cable/km connecting the substations (ensure parallel value is used for single core formats such as triplex)

Z_2 = average substation earthing impedance $(0j + R_B)\Omega$

Short circuits

R8.3 – short overhead lines with earthwire (typically 5 to 20 towers)

$$Z_{CH} = \frac{Z_P(Z_{EB} + Z_P)k^n + (Z_P - Z_Q)(Z_{EB} - Z_P + Z_Q)k^{-n}}{(Z_{EB} + Z_P)k^n - (Z_{EB} - Z_P + Z_Q)k^{-n}}$$

(NOTE: all impedances are in complex notation. Formula as provided in (BS EN 60909-3, 2010). Refer to BS EN 60909 for descriptions of symbols because they differ from those used in this document).

For detailed calculations, a discrete ladder network (iterative) routine or computer software should be used. The self and mutual impedance for the earthwire(s) need to be calculated, accounting for their material, cross sectional area and the circuit geometry.

Short underground cable/substation arrangements.

The approach is as follows:

Where there a significant proportion of the cable is PILCSWA, the resistance is calculated based entirely on this using Formula R6.

Where the majority of the cable is XLPE/EPR/Triplex etc., an approximate approach is to treat all the substation earth resistances as being in parallel and inflate the result by 30% to account for the longitudinal sheath impedance. This is sufficiently accurate for typical cable lengths of 200m to 450m and low sheath impedance. If more than 6 substations are be considered, a higher inflation amount needs to be considered. Detailed calculations will be needed if the substation earth resistances approach 1 ohm or less, because the sheath impedance then becomes significant.

For detailed calculations, a discrete ladder network (iterative) routine or computer software should be used.

Commented [RW42]: here and elsewhere in this Appendix, text has been added to show where the formula came from and would be removed prior to publication

Formatted: Highlight

1107 See also (BS EN 60909-3, 2010) for more details of the calculations for ladder networks,
1108 including non-symmetrical arrangements.

1109 **Formula R9 Accounting for proximity effects**

1110 The resistance R_t in ohms (Ω) of n vertically driven rods set s metres apart may be
1111 calculated from:

1112 $$R_t = \frac{l}{n}\frac{\rho}{2\pi L}\left[log_e\left(\frac{8L}{d}\right) - 1 + \frac{\lambda L}{s}\right]$$

1113 Where:

ρ   is the resistivity of soil, in ohm metres (Ωm);

L is the length of the electrode, in metres (m);

n is the number of rods;

and

λ   is a group factor where: $\lambda = 2\,\boldsymbol{\Sigma}(\frac{l}{2} + \cdots + \frac{l}{n})$

1114 *NOTE*: For larger values of n, λ can be approximated by: $\lambda \simeq 2\,log_e\,\frac{1.781n}{2.818}$

1115 (Source: Sunde, E.D.: Earth conduction effects in transmission systems, Dover Publications, 1967, pp75-79)

1116 Computer software is best used to account for proximity effects where strip electrodes or
1117 PILCSWA type cables run in parallel. An approximation of this effect can be made using
1118 proximity factors such as those illustrated in Table A2.2 below. Strip electrodes of about
1119 120m in uniform soil are a set distance apart. Each provides a resistance of 2Ω in uniform
1120 soil and in the absence of the effect, a parallel resistance of 1Ω would be anticipated. The
1121 table shows the higher resistance and proximity factor that applies, clearly increasing when
1122 the electrodes are closer together.

Separation distance m	Overall resistance Ω	Proximity factor
1	1.57	1.57
5	1.38	1.38
10	1.3	1.3
20	1.22	1.22
50	1.125	1.125
100	1.07	1.07

1123 **Table A2.2 Proximity effect of electrodes run in parallel (calculated using computer
1124 software)**

1125 **Formula R10 Overall earth resistance**

1126 $$Z_E = \left(\frac{1}{R_{Es}} + \frac{1}{R_H} + \frac{1}{Z_{CH1}} + \frac{1}{Z_{CH2}} + \cdots\right)^{-1}$$

1127 **Formula C1 Current rating formula**

1128 For fault currents which are interrupted in less than 5s the cross-section of earthing
1129 conductor or earth electrode shall be calculated from the following formula D.1 (IEC 60287 -
1130 3-1 Ed 1.1b, 1999)

1131 $$A = \frac{I}{K} \sqrt{\frac{t_f}{log_e \left(\frac{\theta_f + \beta}{\theta_i + \beta} \right)}}$$

1132 *(Source: IEC 60949, formula D1)*

1133 where:

A	is the cross-section in mm^2
I	is the conductor current in amperes (RMS value)
t_f	is the duration of the fault in seconds
K	is a constant depending on the material of the current-carrying component; Table D.1 of IEC 60949 provides values for the most common materials assuming an initial temperature of 20°C
β	is the reciprocal of the temperature coefficient of resistance of the current-carrying component at 0°C (see Table below).
θ_i	is the initial temperature in degrees Celsius. Values may be taken from (IEC 60287-3-1 Ed. 1.1 b : 1999, Electric cables - Calculation of the current rating - Part 3-1: Sections on operating conditions - Reference operating conditions and selection of cable type, 1999). If no value is laid down in the national tables, 20°C as ambient ground temperature at a depth of 1m should be adopted.
θ_f	Is the final temperature in degrees Celsius

1134

Surface potential formulae

For substations with separately earthed fence and normal buried grid depths (typically 0.6 m)

Formula P1 External touch potential at the edge of the electrode

$$E_{t(grid)} = \frac{k_e \cdot k_d \cdot \rho \cdot I}{L} \text{ (V) or } L = \frac{k_e \cdot k_d \cdot \rho \cdot I}{E_{touch}} \text{ (m)}$$

$$k_e = \frac{1}{\pi}\left(\frac{1}{2}log_e\frac{h}{d} + \frac{1}{2h} + \frac{1}{(0.5 + D)} + \frac{1}{D}(1 - 0.5^{n-2})\right)$$

k_e is a factor that allows for the effect of a uniformly distributed electrode current over the grid and is given by:

h	=	grid depth (m)

d = equivalent diameter of conductor $= \dfrac{\text{circumference of conductor}}{\pi}$ (m)

ρ = soil resistivity (Ω m)

I = total current passing to ground through electrode (A)

D = average spacing between parallel grid conductors (m)

$$n = (n_A \times n_B)^{1/2}$$

where n_A = number of parallel grid conductors in one direction

where n_B = number of parallel grid conductors in the other direction

k_d is a factor, which modifies k_e to allow for the non-uniform distribution of electrode current, and is given by:

$$k_d = \left(0.7 + 0.3\frac{L}{L_p}\right)$$

where

L = total length of buried electrode conductor including rods if connected (m)

L_p = perimeter length of buried electrode conductor including rods if connected (m)

I = total current passing to ground through electrode (A)

E_{touch} = resulting "touch" potential or, when assessing length L, the safe "touch" potential from Figure 2

1159 **Formula P2 External 'Touch' potential at the fence**

1160 The ground current density is significantly diminished at the fence compared to that at the
1161 edge of the grid electrode. As a result, a new factor, k_f, based on a two metre separation
1162 between fence and grid electrode, is applied in place of k_e in the above formulae.

1163 Hence:

1164 $$U_{\text{VT(fence)}} = \frac{k_f \cdot k_d \cdot \rho \cdot I}{L}(V) \ or \ L = \frac{k_f \cdot k_d \cdot \rho \cdot I}{E_{touch}}(m)$$

1165 where $k_f = 0.26 k_e$

1166 Substation with integrally earthed fence

1167 There are two situations to be considered. The first is where the fence is situated at the
1168 edge of the substation electrode. The second has a peripheral electrode conductor buried
1169 half a metre below the surface, one metre beyond the fence and regularly bonded to it.

1170 External touch potential at fence with no external peripheral electrode

1171 $E_{t(fence)}$E_t (fence) is the same as $E_{t(grid)}$E_t (grid) using P1 as above.

1172 **Formula P3 External touch potential at fence with external buried peripheral**
1173 **conductor 1m from fence**

1174 $$U_{\text{VT(fence)}} = \frac{k_{fe} \cdot k_d \cdot \rho \cdot I}{L}(V) \ or \ L = \frac{k_{fe} \cdot k_d \cdot \rho \cdot I}{E_{touch}}(m)$$

1175 Where $k_{fe} = \left(\frac{1}{2}log_e\frac{h}{d} - \frac{1}{4}log_e(S^2 + 0.5^2)^2 + \frac{1}{4}log_e(S^4 + S^2)\right)$

1176 h and d are as in formula P1

1177 S = distance between the outermost buried grid conductor and the next nearest parallel
1178 conductor (m)

1179

1180 **Formula P4 Touch voltage within grid (from IEEE80)**

1181 <mark>Notes:</mark>

1182 <mark>Formula 16.5.1 (quite complex and has a number of correction factors)</mark>
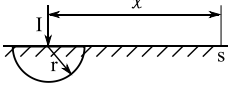

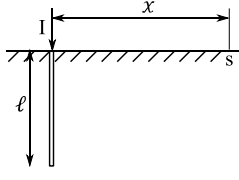

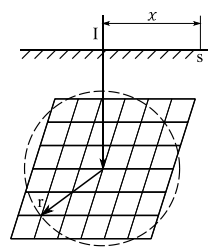

1183 <mark>Annex D has simpler formulae.</mark>

1184 **Formula P5 Step voltage on outside edge of grid**

1185 $U_{VS} = \dfrac{\rho I_F}{2\pi r}\left(arcsin\dfrac{r}{x} - arcsin\dfrac{r+1}{x}\right)$ where $r = \dfrac{\rho}{4R_E}$

1186

1187 **Formula P6 Voltage profile around earth electrode**

COLUMN	P6.1	P6.2	P6.3
ELECTRODE DESCRIPTION	HEMISPHERE	VERTICAL ROD	BURIED GRID
CONFIGURATION			
VOLTAGE ON THE SURFACE OF THE GROUND AT POINT 'S' WITH RESPECT TO TRUE EARTH	$V_S = \dfrac{\rho I}{2\pi x}$	$V_S = \dfrac{\rho I}{2\pi \ell}\log_e\left(\dfrac{\ell}{x} + \sqrt{1 + \dfrac{\ell^2}{x^2}}\right)$	$V_S = \dfrac{\rho I}{2\pi \ell}\arcsin\dfrac{r}{x}$ where $r = \dfrac{\rho}{4R_g}$ $\arcsin\dfrac{r}{x}$ (in radians)

1188

1189 **Formula P7 Calculation of specific external potential contours**

1190 $$Z_x = \sqrt{\frac{A}{\pi} \left[\left(sin \frac{V_x \pi}{2U_E} \right)^{-1} - 1 \right]}$$

1191 where Z_x is the distance in metres to a point where the surface potential is V_x volts.

1192 $$Z_{430} = \sqrt{\frac{A}{\pi} \left[\left(sin \frac{215\pi}{U_E} \right)^{-1} - 1 \right]}$$

1193 $$Z_{650} = \sqrt{\frac{A}{\pi} \left[\left(sin \frac{325\pi}{U_E} \right)^{-1} - 1 \right]}$$

1194 where Z_{430} and Z_{650} are in metres.

1195 A = superficial area of grid electrode in square metres.

1196 U_E = earth potential rise in volts.

1197 These formulae apply on the basis that the earthing installation may be treated as equivalent
1198 to a symmetrical grid.

1199 Substation fences are usually earthed independently from the main earthing system and may
1200 be up to 2m from it. By using the above formulae as the "hot zone" radii, a factor of safety is
1201 introduced when they are applied measured from the substation fence. Some discretion may
1202 be necessary in assessing the "hot zone" radius of a substation where the fence is bonded to
1203 the earthing installation or there is a large distance from the fence to the edge of the earthing
1204 system.

1205 Clearly this formula does not apply when U_E is lower than the voltage contour of interest.

1209 **APPENDIX D – Formulae for determination of ground return current for earth**
1210 **faults on metal sheathed cables**

1211 The current in the core of a single-core cable or the unbalance of current in the cores of a
1212 multicore cable induces a voltage in the metallic sheath/armour of the cable. If the
1213 sheath/armour is connected to earth at each end of its length, a current will be driven through
1214 the sheath/armour earth loop which constitutes part of the earth fault current returning from
1215 the fault, the remainder being that returning in the ground. The quantity of current returning
1216 in the cable sheath/armour is, inter alia, dependent on the location of the cable in the system
1217 with respect to the source of fault current infeed and to the position of the fault as well as on
1218 the values of the sheath/armour terminating earth resistances.

1219 Formulae for the computation of the ground current are given below, in respect of a cable
1220 terminated and earthed at points A and B.

1221 1a. Three-core cable (unarmoured), source of infeed at point A and fault at point B. See
1222 diagram Fig. 7.

1224
$$I_{Es} = -I_F \left[\frac{l(z_c - z_{mp,c})}{lz_c + R_A + R_B} \right] = -I_F \left[\frac{lr_c}{lz_c + R_A + R_B} \right]$$

1223

1225 1b. Three-core cable (armoured), source of infeed at point A and fault at point B. See
1226 diagram Figs. 7 and S.

1227
$$I_{Es} = -I_F \left[\frac{l\left(\frac{r_c \times r_a}{r_c + r_a}\right)}{l\left(\left(\frac{r_c \times r_a}{r_c + r_a}\right) + r_e + j\omega(L_c + L_a)\right) + R_A + R_B} \right]$$

1228 2a. Three-core cable (unarmoured), source of infeed beyond point A and fault beyond point
1229 B. See diagram Fig. 9.

1230
$$I_{Es} = -I_F \left[\frac{l(z_c - z_{mp,c}) + R_A + R_B}{lz_c + R_A + R_B} \right] = -I_F \left[\frac{lr_c + R_A + R_B}{lz_c + R_A + R_B} \right]$$

1231 2b. Three-core cable (armoured), source of infeed beyond point A and fault beyond point B.
1232 See diagram Figs. 9 and 10.

1233
$$I_{Es} = -I_F \left[\frac{l\left(\frac{r_c \times r_a}{r_c + r_a}\right) R_A + R_B}{l\left(\left(\frac{r_c \times r_a}{r_c + r_a}\right) + r_e + j\omega(L_c + L_a)\right) + R_A + R_B} \right]$$

1234

1235 3a. Three-core cable (unarmoured), source of infeed beyond point A and fault at point B, or
1236 source of infeed at point B and fault beyond point A. See diagram Fig. 12.

1237
$$I_{Es} = -I_F \left[\frac{l(z_c - z_{mp,c}) + R_A}{lz_c + R_A + R_B} \right] = -I_F \left[\frac{lr_c + R_A}{lz_c + R_A + R_B} \right]$$

1238 3b. Three-core cable (armoured), source of infeed at point A and fault at point B, or source of
1239 infeed at point B and fault beyond point A. See diagram Figs. 11 and 13.

1240
$$I_{Es} = -I_F \left[\frac{l\left(\frac{r_c \times r_a}{r_c + r_a}\right) R_A}{l\left(\left(\frac{r_c \times r_a}{r_c + r_a}\right) + r_e + j\omega(L_c + L_a)\right) + R_A} \right]$$

1241 4. Three single-core cables, source of infeed at point A and fault at point B; the cable sheaths
1242 are referenced 1, 2, 3. See diagram Fig. 14, Evaluate sheath currents 11, 12 and 13 and
1243 determine IEs from the following:

1244
$$\begin{bmatrix} (R_A + lz_{c1} + R_B) & (R_A + lz_{m1,2} + R_B) & (R_A + lz_{m1,3} + R_B) \\ (R_A + lz_{m1,2} + R_B) & (R_A + lz_{c2} + R_B) & (R_A + lz_{m2,3} + R_B) \\ (R_A + lz_{m1,3} + R_B) & (R_A + lz_{m2,3} + R_B) & (R_A + lz_{c3} + R_B) \end{bmatrix} \begin{bmatrix} I_1 \\ I_2 \\ I_3 \end{bmatrix} = -I_F \begin{bmatrix} (R_A + lz_{mp,1} + R_B) \\ (R_A + lz_{mp,2} + R_B) \\ (R_A + lz_{mp,3} + R_B) \end{bmatrix}$$

1245 5. Three single-core cables, source of infeed beyond point A and fault beyond point B. See
1246 diagram Fig. 15.

1247 Evaluate sheath currents 11, I2 and 13 and determine I_{Es} from the following:

1248
$$\begin{bmatrix} \text{IMPEDANCE COEFFICIENTS} \\ \text{AS IN (4) ABOVE} \end{bmatrix} \begin{bmatrix} I_1 \\ I_2 \\ I_3 \end{bmatrix} = -I_F \begin{bmatrix} (lz_{mp,1}) \\ (lz_{mp,2}) \\ (z_{mp,3}) \end{bmatrix}$$

1249 6. Three single-core cables, source of infeed beyond point A and fault at point B, or source of
1250 infeed at point B and fault beyond point A. See diagrams Figs. 16 and 17.

1251 Evaluate sheath currents 11, 12 and 13 and determine I_{Es} from the following:

1252
$$\begin{bmatrix} \text{IMPEDANCE COEFFICIENTS} \\ \text{AS IN (4) ABOVE} \end{bmatrix} \begin{bmatrix} I_1 \\ I_2 \\ I_3 \end{bmatrix} = -I_F \begin{bmatrix} (lz_{mp,1} + R_B) \\ (lz_{mp,2} + R_B) \\ (z_{mp,3} + R_B) \end{bmatrix}$$

1253 The parameters used in the above formulae are as given in the list of symbols shown in
1254 Section 3.1 or as defined below.

1255 The quantities z_c ; z_{c1} ; z_{c2} ; z_{c3} are the sheath to earth self impedances at 50 Hz.

1256
$$= r_c + \left(49.4 + j62.8 \, log_e \frac{93.2\sqrt{\rho}}{c_g} \right) \times \frac{10^{-3}\Omega}{km}$$

1257 where c_g is the GMR of the sheath in metres.

1258 The quantity R_E is the resistive component of the ground return path of the sheath to earth self
1259 impedance.

1260 $\quad = 5\pi^2 10^{-3} \Omega/\text{km}$

1261 $\quad = \left(0.2 \, log_e \dfrac{93.2\sqrt{\rho}}{c_g}\right) \times 10^{-3} \Omega/km$

1262 The quantity L_c is the inductive component of the sheath to earth self impedance.

1263 The quantity L_a is the effective inductance of the armour wire.

1264 $\quad = \left(\dfrac{0.4\mu t}{d_i + t}\right) \times \dfrac{10^{-3} H}{km}$

1265 Where t is the thickness of the armour wire in metres.

1266 $\qquad d_i$ is the internal diameter of the armour wire in metres.

1267 $\qquad \mu$ is the relative permeability of the armour wires

1268
1269 The quantities $z_{mp,c}$; $z_{mp,1}$; $z_{mp,2}$ and $z_{mp,3}$ are the faulty conductor to sheath mutual
1270 impedances and $z_{m1,2}$; $z_{m1,3}$ and $z_{m2,3}$ are the sheath-to-sheath mutual impedances at 50 Hz.

1271 $\quad = \left(49.4 + j62.8 \, log_e \dfrac{93.2\sqrt{\rho}}{d}\right) \times \dfrac{10^{-3} \Omega}{km}$

1272 where d is the centre to centre distance in metres between the conductors/sheaths.

1273 In calculating $z_{mp,c}$; $z_{mp,1}$; $z_{mp,2}$ and $z_{mp,3}$ the value of d has been substituted for c_g (where c_g
1274 is the GMR of the sheath in metres).

1275 In the following table, the values of z_c and $z_{mp,c}$ for three-core cables in common use are listed
1276 for an assumed value of p of 100 Ωm.

System Voltage / Cable Type		Impedances in Ω/km for cables of Cross-sectional Area of:					
		0.1 in2		185 sq mm		300 sq mm	
		z_c	$z_{mp,c}$	z_c	$z_{mp,c}$	z_c	$z_{mp,c}$

1291 **APPENDIX G – Chain impedance of standard 132kV earthed tower lines**

1292 The table below provides chain impedances for a 132kV L4 type construction with three
1293 towers/km and a horse earthwire (approx 70mm^2 aluminium ACSR, to BS215 pt5 1970).

1294 Longitudinal impedance of earthwire is 0.443 + j 0.757 ohm/km (calculated using Carson
1295 Clem formula).

1296 The values assume more than 20 towers in series.

Footing resistance (ohm)	Chain impedance r + j x ohm	Chain impedance Z ∠° ohm
1	0.543+j0.414	0.683∠37.35
2	0.737+j0.52	0.902∠35.21
3	0.886+j0.603	1.072∠34.24

1298 **APPENDIX H – Sample calculations showing the effect on the ground return**
1299 **current for change in the separation distance between three**
1300 **single core cables laid flat or in trefoil**

1301 For the studies, three representative cables were selected for 11kV and 132kV voltage
1302 levels. Their details are given in Table A8.1.

Operating voltage (kV)	Cable number	Phase conductor size mm²	Insulation type	Insulation thickness mm	Core / Screen type + size mm²	Reference cable code
132	1	630	XLPE	15	Lead	132_01_12
132	2	630	XLPE	21	Lead	132_01_13
132	3	630	XLPE	15	Copper wire 135	132_01_17
11	4	70	EPR		Copper wire 12	11_3_SZ
11	5	300	EPR		Copper wire 35	11_225_EPR
11	6	300	XLPE		Copper wire 70	11_21_S

1303 **Table A8.1 Technical details of cables modelled**

1304 The geometric arrangements considered are Trefoil and Flat. They are analysed on the
1305 basis that they are installed such that the cables are touching and again assuming they are a
1306 symmetrical distance 3 x D apart (where D is the outer cable diameter in mm). See Table
1307 A8.2 for details.
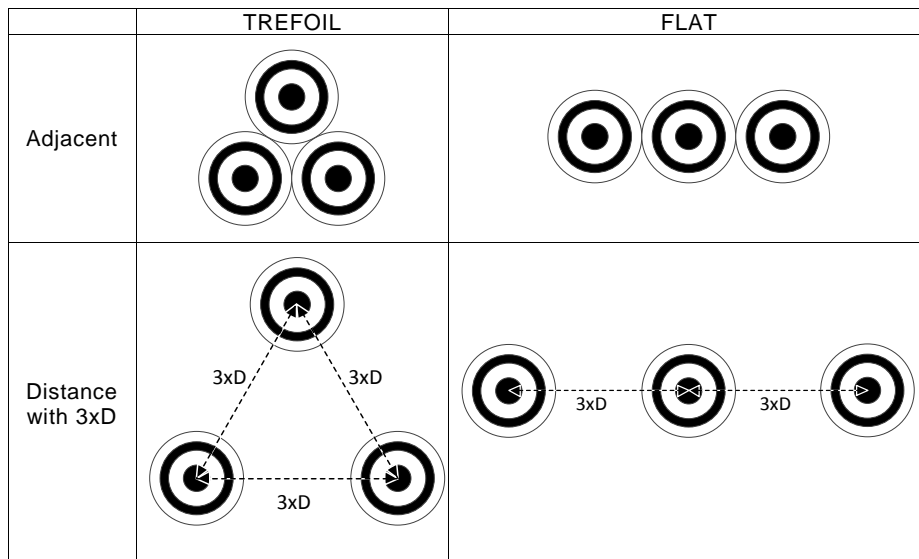

1308 **Table A8.2 The geometric placement of cables**

1309 The 132kV cables were selected to show the difference that the sheath/screen configuration
1310 makes for the same size phase conductor. One standard cable contains a tubular conductor
1311 made of aluminum foil in addition to its stranded copper conductor. The cross-sectional view
1312 for this cable (trefoil format) is shown in Figure A8.1.
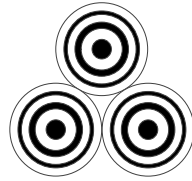

1313

1314 **Figure A8.1 Cross-sectional view for Cable 3**

1315 The circuit used to simulate the different cable arrangements and determine the effect on the
1316 earth return current is shown in Figure A8.2
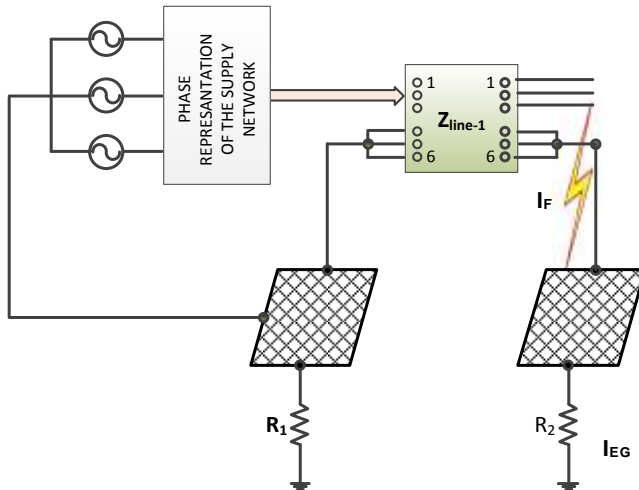

1317

1318 **Figure A8.2 Circuit used for analysis purposes**

1319 Using the circuit described, studies were carried out for each of the cables of Table 1, and
1320 the ground return current calculated for a set range of cable lengths. For each cable, four
1321 sets of studies were carried out, i.e. one for each physical arrangement of the individual
1322 cables.

1323 The results are shown in Figures A8.3 and A8.4, with the ground return current I_{ES} shown as
1324 a percentage of the total earth fault current I_F.

1325   **Cable 1: 630mm² with 15mm XLPE, lead sheathed**

1326   **Cable 2: 630mm² with 21mm XLPE, lead sheathed**

1327   **Cable 3: 630mm² with 15mm XLPE and composite screen/sheath**
1328   **(135mm²Cu and 45mm² A$_l$)**
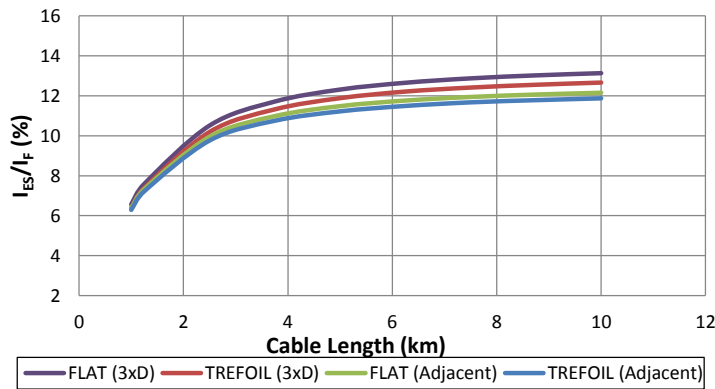

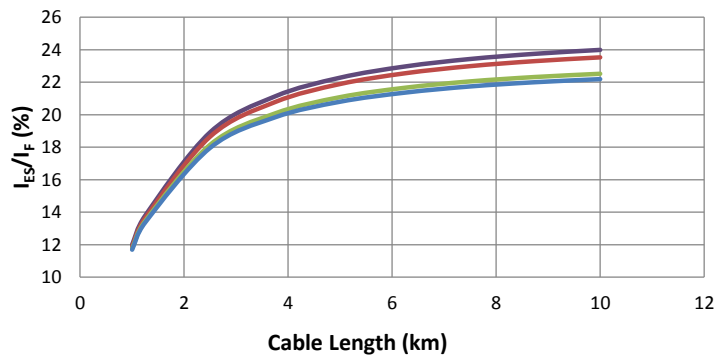

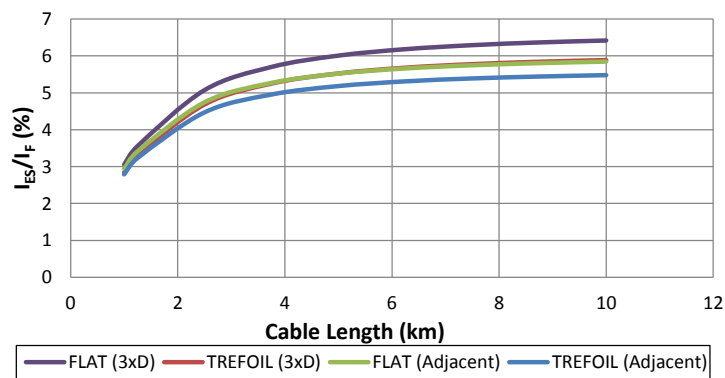

1329   **Figure A8.3 Ground return current (I_{ES}) as a percentage of (I_F) against circuit length for**
1330   **difference 132kV cable installation arrangements**

1331   **Cable 4: (70mm² with 12mm² Cu screen)**

1332   **Cable 5: (300mm² with 35mm² Cu screen)**

1333   **Cable 6: (300mm² with 70mm² Cu screen)**

1334   **Figure A8.4 Ground return current (I_{ES}) as a percentage of (I_F) against circuit length for**
1335   **different 11kV cable installation arrangements**

The results show that earth return current increases when the distance between adjacent cables is increased. The percentage increase in I_{gr} compared to the touching trefoil arrangement is shown in tables A8.3 and A8.4. The difference is seen to increase with circuit length and cable separation distance.

	Cable 1		Cable 2		Cable 3	
	1 km	10 km	1 km	10 km	1 km	10 km
Difference trefoil (3xD) - trefoil (%)	1.7	7.0	1.6	7.1	1.8	7.5
Difference flat - trefoil (%)	1.3	2.4	1.3	2.4	5.5	6.7
Difference flat (3xD) - trefoil (%)	4.2	11.0	4.2	11.1	9.5	17.1

Table A8.3 Effect of physical cable arrangement on ground return current I_{ES} for 132 kV cables

	Cable 4		Cable 5		Cable 6	
	1 km	10 km	1 km	10 km	1 km	10 km
Difference trefoil (3xD) - trefoil (%)	1.1	3.6	1.5	6.0	1.7	6.7
Difference flat - trefoil (%)	0.2	0.7	0.6	1.5	1.4	2.4
Difference flat (3xD) - trefoil (%)	1.4	4.5	2.6	8.1	4.4	10.6

Table A8.4 Effect of physical cable arrangement on ground return current I_{ES} for 11kV cables

Conclusions:

From figures A8.3 and A8.4, the following can be deduced:-

1. Touching trefoil is the most effective arrangement in terms of minimising the ground return current. This is as expected, due to the more symmetrical arrangement and its impact on maximising mutual coupling effects. The ground return current increases in all cases in the order touching trefoil, touching flat, 3 x D trefoil and 3 x D flat.

2. The difference between trefoil and flat arrangements is less than 0.5% of the total and can be disregarded for most studies.

3. Increasing the separation between the individual cables generally increases the ground return current by less than 1% of the total.

4. The decrease in cable core insulation thickness from 21mm (in older cables) to 15mm does reduce the ground return current, but by an insignificant amount in relation to other factors (such as measurement errors) and can be ignored for the majority of cases.

5. The two dominant factors influencing the ground return current in these studies are the circuit length and the electrical conductivity of the sheath/screen. The latter is most visibly seen when comparing the 132kV composite screen (copper and aluminium) against a similar cable with a lead screen. The ground return current is more than doubled for the latter. The same effect is apparent with the 11kV cables and cable 4 with its relatively small

1362 screen of 12mm2/cable shows the importance of considering the screen size because the
1363 ground return current can reach almost 54% for this cable.

1364 Tables A8.3 and A8.4 are included for completeness and show the increase in the actual
1365 ground return current with changes in physical arrangement, as a percentage of the ground
1366 return current for the touching trefoil arrangement.
